## Depth-zero supercuspidal *L*-packets and their stability

By STEPHEN DEBACKER and MARK REEDER

In this paper we verify the local Langlands correspondence for pure inner forms of unramified *p*-adic groups and tame Langlands parameters in "general position". For each such parameter, we *explicitly* construct, in a natural way, a finite set ("*L*-packet") of depth-zero supercuspidal representations of the appropriate *p*-adic group, and we verify some expected properties of this *L*-packet. In particular, we prove, with some conditions on the base field, that the appropriate sum of characters of the representations in our *L*-packet is stable; no proper subset of our *L*-packets can form a stable combination. Our *L*-packets are also consistent with the conjectures of B. Gross and D. Prasad on restriction from  $SO_{2n+1}$  to  $SO_{2n}$  [24].

These *L*-packets are, in general, quite large. For example,  $\text{Sp}_{2n}$  has an *L*-packet containing  $2^n$  representations, of which exactly two are generic. In fact, on a quasi-split form, each *L*-packet contains exactly one generic representation for every rational orbit of hyperspecial vertices in the reduced Bruhat-Tits building. When the group has connected center, every depth-zero generic supercuspidal representation appears in one of these *L*-packets.

We emphasize that there is nothing new about the representations we construct. They are induced from Deligne-Lusztig representations on subgroups of finite index in maximal compact mod-center subgroups, see [42], [44], [61]. The point here is to assemble these representations into L-packets in a natural and explicit way and to verify that these L-packets have the required properties.

To explain further, we need some notation. Let k be a p-adic field of characteristic zero, let K be a maximal unramified extension of k, let  $\Gamma = \text{Gal}(K/k)$ , and let  $\text{Frob} \in \Gamma$  be a Frobenius element. Let  $\mathcal{W}_t$ ,  $\mathcal{I}_t$  be the tame Weil group of k and its inertia subgroup. Let  $\mathbf{G}$  be a connected reductive k-group which is K-split and k-quasi-split. To simplify the exposition, we assume in this introduction that  $\mathbf{G}$  is semisimple. Let  $G := \mathbf{G}(K)$ , and let  $\mathbf{F}$  be the action of Frob on G, arising from the given k-structure on  $\mathbf{G}$ .

In the spirit of local class field theory, we construct both the "geometric" and "*p*-adic" sides of our local Langlands correspondence, and make an explicit connection between the two sides.

We start with the geometric side. The action of F on the root datum of **G** gives rise to an automorphism  $\hat{\vartheta}$  of the Langlands dual group  $\hat{G}$ . The Langlands parameters considered in this paper are continuous homomorphisms

$$\varphi: \mathcal{W}_t \longrightarrow \langle \hat{\vartheta} \rangle \ltimes \hat{G},$$

(for the discrete topology on  $\langle \hat{\vartheta} \rangle \ltimes \hat{G}$ ) whose centralizer in  $\hat{G}$  is finite, and such that  $\varphi(\text{Frob})$  is a semisimple element in  $\hat{\vartheta}\hat{G}$ , and  $\varphi(\mathcal{I}_t)$ , a priori a finite cyclic group, is generated by a regular semisimple element in  $\hat{G}$ . This latter condition is what we mean by "general position". It implies that  $\varphi(\mathcal{I}_t)$  is contained in a unique maximal torus  $\hat{T} \subset \hat{G}$ . The element  $\varphi(\text{Frob})$  normalizes  $\hat{T}$ , acting via an element of the form  $\hat{\vartheta}\hat{w}$ , where  $\hat{w}$  belongs to the Weyl group of  $\hat{T}$  in  $\hat{G}$ . Moreover, the centralizer of  $\varphi$  is the finite abelian group

$$C_{\varphi} := \hat{T}^{\hat{\vartheta}\hat{w}}$$

of fixed-points of  $\varphi(\text{Frob})$  in  $\hat{T}$ .

For each irreducible character  $\rho \in \operatorname{Irr}(C_{\varphi})$ , we will define a representation of the group of k-points of a certain inner form of **G**.

First, we parametrize  $\operatorname{Irr}(C_{\varphi})$  as follows. The automorphisms  $\hat{\vartheta}$  and  $\hat{w}$ induce dual automorphisms  $\vartheta$  and w of the character group  $X := X^*(\hat{T})$ , and each  $\lambda \in X$  determines a character  $\rho_{\lambda} \in \operatorname{Irr}(C_{\varphi})$  by restriction from  $\hat{T}$  to  $\hat{T}^{\hat{\vartheta}\hat{w}}$ . Thus we have an isomorphism

$$X/(1-w\vartheta)X \xrightarrow{\sim} \operatorname{Irr}(C_{\varphi}), \quad \lambda \mapsto \rho_{\lambda}.$$

Next, for each  $\lambda \in X$  we construct an unramified cocycle  $u_{\lambda} \in Z^{1}(\Gamma, G)$ , hence an inner twist of **G** with Frobenius  $F_{\lambda} = \operatorname{Ad}(u_{\lambda}) \circ F$ , along with an irreducible depth-zero supercuspidal representation  $\pi_{\lambda}$  of  $G^{F_{\lambda}}$ .

The cocycle  $u_{\lambda}$  is found as follows. Let W be the affine Weyl group of G, acting on the apartment  $\mathcal{A} = \mathbb{R} \otimes X$  in the Bruhat-Tits building  $\mathcal{B}(G)$  of G. The character  $\lambda \in X$  determines a translation  $t_{\lambda} \in W$ . Since  $\hat{T}^{\hat{\vartheta}\hat{w}}$  is finite, it follows that the operator  $t_{\lambda}w\vartheta$  has a unique fixed-point  $x_{\lambda} \in \mathcal{A}$ . If we choose an alcove  $C_{\lambda} \subset \mathcal{A}$  containing  $x_{\lambda}$  in its closure, we can then uniquely write

(1) 
$$t_{\lambda}w\vartheta = w_{\lambda}y_{\lambda}\vartheta,$$

where  $w_{\lambda}$  belongs to the "parahoric subgroup" of W at  $x_{\lambda}$  and  $y_{\lambda} \in W$  satisfies  $y_{\lambda}\vartheta \cdot C_{\lambda} = C_{\lambda}$ . The cocycle  $u_{\lambda} : \Gamma \longrightarrow G$  sends Frob to an appropriately chosen representative of  $y_{\lambda}$  in G.

Now for the representation  $\pi_{\lambda}$ . The point  $x_{\lambda}$  is  $F_{\lambda}$ -stable, and is in fact a vertex in  $\mathcal{B}(G^{F_{\lambda}})$ . The parahoric subgroup  $G_{\lambda}$  of G at  $x_{\lambda}$  is  $F_{\lambda}$ -stable, and  $G_{\lambda}^{F_{\lambda}}$  is a maximal parahoric subgroup of  $G^{F_{\lambda}}$ . The representation  $\pi_{\lambda}$  of  $G^{F_{\lambda}}$  is compactly-induced from a representation  $\kappa_{\lambda}$  of  $G_{\lambda}^{F_{\lambda}}$ .

This  $\kappa_{\lambda}$  is obtained as follows. The element  $w_{\lambda}$  determines an  $F_{\lambda}$ -anisotropic torus  $T_{\lambda}$  of G with  $T_{\lambda}^{F_{\lambda}} \subset G_{\lambda}$ . By the depth-zero Langlands correspondence

for tori (known, but reproved in Chapter 4.3 below), we can associate to  $(\varphi, \lambda)$  a depth-zero character  $\chi_{\lambda}$  of  $T_{\lambda}^{F_{\lambda}}$ , whence a Deligne-Lusztig representation

$$\kappa_{\lambda} := \pm R_{T_{\lambda}}^{G_{\lambda}} \chi_{\lambda}.$$

Thus, for each  $\lambda \in X$ , we define

$$\pi_{\lambda} := \operatorname{ind}_{G_{\lambda}^{F_{\lambda}}}^{G^{F_{\lambda}}} \kappa_{\lambda},$$

using compact (equivalently, smooth) induction, and prove that  $\pi_{\lambda}$  is an irreducible representation of  $G^{F_{\lambda}}$ . Of course, we now have infinitely many groups  $G^{F_{\lambda}}$  and representations  $\pi_{\lambda}$ , whereas the *L*-packet  $\Pi(\varphi)$  should be parametrized by the finite set  $\operatorname{Irr}(C_{\varphi})$ .

However, according to Vogan's idea of "representations of pure-inner forms" [62], we must take into account the natural *G*-action on pairs  $(u, \pi_u)$ , where  $u \in Z^1(\Gamma, G)$  and  $\pi_u$  is a representation of  $G^{F_u}$  (here  $F_u = \operatorname{Ad}(u) \circ F$ ). We prove that the *G*-orbit  $[u_\lambda, \pi_\lambda]$  is independent of all choices made in the construction, and that for  $\lambda, \mu \in X$ , we have

$$[u_{\lambda}, \pi_{\lambda}] = [u_{\mu}, \pi_{\mu}] \quad \Leftrightarrow \quad \rho_{\lambda} = \rho_{\mu} \in \operatorname{Irr}(C_{\varphi}).$$

Thus, our construction leads to an *L*-packet  $\Pi(\varphi)$  in the form of equivalence classes:

$$\Pi(\varphi) = \{ [u_{\lambda}, \pi_{\lambda}] : \rho_{\lambda} \in \operatorname{Irr}(C_{\varphi}) \}.$$

We have a partition

$$\Pi(\varphi) = \coprod_{\omega \in H^1(\Gamma, G)} \Pi(\varphi, \omega)$$

where  $\Pi(\varphi, \omega)$  consists of the classes  $[u_{\lambda}, \pi_{\lambda}]$  with  $u_{\lambda} \in \omega$ . Let

$$\operatorname{Irr}(C_{\varphi}) = \coprod_{\omega \in H^1(\Gamma, G)} \operatorname{Irr}(C_{\varphi}, \omega)$$

be the corresponding partition of  $Irr(C_{\varphi})$ .

The first expected property of  $\Pi(\varphi)$  is that  $\operatorname{Irr}(C_{\varphi}, \omega)$  should be the fiber over  $\omega$  under the composition

(2) 
$$\operatorname{Irr}(C_{\varphi}) \longrightarrow \operatorname{Irr}(\hat{Z}^{\hat{\vartheta}}) \xrightarrow{\sim} H^{1}(\Gamma, G),$$

where the first map is restriction, the second map is Kottwitz' isomorphism [34], and  $\hat{Z}$  is the center of  $\hat{G}$ . This amounts to proving that the map described in (2) sends  $\rho_{\lambda} \in \operatorname{Irr}(C_{\varphi})$  to the class of  $u_{\lambda}$  in  $H^1(\Gamma, G)$ . For this, and other purposes, we need a very explicit description of Kottwitz' isomorphism on the level of cocycles. Chapter 2 contains a simple proof of Kottwitz' isomorphism in the form we need, along with related facts used in the proof of stability.

The second expected property of  $\Pi(\varphi)$  is that the ratio of formal degrees

$$\frac{\deg(\pi_{\lambda})}{\deg(\operatorname{St}_{\lambda})},$$

where  $\operatorname{St}_{\lambda}$  is the Steinberg representation of  $G^{F_{\lambda}}$ , should be independent of  $\lambda \in X$ . This is proved by a direct calculation in Chapter 5.

The third expected property of  $\Pi(\varphi)$  is that  $\pi_0$  (here  $\lambda = 0$ ) should be generic. This is true. In fact, we determine all generic representations in  $\Pi(\varphi)$ , and show that they are in natural bijection with rational classes of hyperspecial vertices in the reduced building of G. En route, we classify all depth-zero supercuspidal generic representations of unramified groups; see Chapter 6. There is a more general conjecture, due to B. Gross and D. Prasad [23], about which Whittaker models are afforded by the generic representations in  $\Pi(\varphi)$ . This conjecture is verified for  $\Pi(\varphi)$  in [19].

We illustrate the construction and above-mentioned properties, in Chapter 13, with a "canonical example" of L-packets arising from the opposition involution.

The rest of our paper is devoted to the fourth expected property, namely, the stability of  $\Pi(\varphi, \omega)$ .

We now consider L-packets from the p-adic side. Let **G** be any connected reductive K-split k-group with Frobenius automorphism F on G. Take a pair  $(S, \theta)$ , where  $S = \mathbf{S}(K)$  is the group of K-points in an unramified k-anisotropic maximal torus **S** in **G** and  $\theta$  is a depth-zero character of  $S^F = \mathbf{S}(k)$ . The group  $S^F$  has a unique fixed-point  $x \in \mathcal{B}(G^F)$ . We have a Deligne-Lusztig virtual character  $R_{S,\theta}^{G_x}$  of the parahoric subgroup  $G_x^F$ , which we lift to a class function  $R(G, S, \theta)$  on the set of regular semisimple elements of  $G^F$ , using Harish-Chandra's character integral. One checks that  $R(G, S, \theta)$  depends only on the  $G^F$ -orbit  $\hat{\mathcal{T}}$  of the pair  $(S, \theta)$ . For  $(S, \theta) \in \hat{\mathcal{T}}$ , we define

$$R(G, \tilde{T}) := R(G, S, \theta).$$

We say that two pairs  $(S_1, \theta_1), (S_2, \theta_2)$  as above are *G*-stably-conjugate if there is  $g \in G$  such that  $\operatorname{Ad}(g)$  sends  $(S_1^F, \theta_1)$  to  $(S_2^F, \theta_2)$ . Each *G*-stable class  $\hat{\mathcal{T}}_{st}$  of pairs  $(S, \theta)$  is a finite disjoint union

$$\hat{\mathcal{T}}_{\mathrm{st}} = \hat{\mathcal{T}}_1 \sqcup \cdots \sqcup \hat{\mathcal{T}}_n$$

of  $G^F$ -orbits. We consider the function

$$R(G, \hat{\mathcal{T}}_{\mathrm{st}}) := \sum_{i=1}^{n} R(G, \hat{\mathcal{T}}_{i}).$$

Our aim is to prove that  $R(G, \hat{T}_{st})$  is a stable class-function on the set of strongly regular semisimple elements in  $G^F$ .

But first, we relate  $R(G, \hat{T}_{st})$  to the *L*-packets constructed previously on the geometric side. To do this, we must put the representations in  $\Pi(\varphi)$  in "normal form", as follows. We fix  $\omega \in H^1(\Gamma, G)$ , and choose  $u \in \omega$ . For each  $\lambda \in X$ , with  $u_{\lambda} \in \omega$ , there is  $m_{\lambda}$  in *G* such that  $\operatorname{Ad}(m_{\lambda})$  sends  $G^{F_{\lambda}}$  to  $G^{F_u}$ . For each  $\rho \in \operatorname{Irr}(C_{\varphi}, \omega)$ , we define

$$\pi_u(\varphi, \rho) := \operatorname{Ad}(m_\lambda)_* \pi_\lambda$$

799

where  $\lambda \in X$  is such that  $\rho_{\lambda} = \rho$ . Then  $\pi_u(\varphi, \rho)$  is a representation of  $G^{F_u}$  whose isomorphism class is independent of the choices of  $\lambda$  and  $m_{\lambda}$ . The "normalized" *L*-packet is then defined as

$$\Pi_u(\varphi) := \{ \pi_u(\varphi, \rho) : \rho \in \operatorname{Irr}(C_{\varphi}, \omega) \};$$

it consists of representations of the fixed group  $G^{\mathbf{F}_u}$ .

The comparison between the *p*-adic and geometric sides consists in proving that the sum of characters in  $\Pi_u(\varphi)$  is, up to a constant factor, a function of the form  $R(G, \hat{T}_{st})$  for an appropriate  $\hat{T}_{st}$ . This involves an explicit parametrization of the *G*-stable classes of pairs  $(S, \theta)$ , in terms of characters  $\lambda \in X$ . This parametrization follows naturally from our study of Kottwitz' isomorphism in Chapter 2.

Now, to prove stability for our *L*-packets, it remains to prove that the functions  $R(G, \hat{\mathcal{T}}_{st})$  are stable. The first main step is a reduction formula, using the topological Jordan decomposition. This reduction becomes trivial on the set of strongly regular topologically semisimple elements in  $G^F$ , proving stability there without any restrictions on the residue characteristic.

To prove stability everywhere, we must examine the restriction of  $R(G, \hat{T}_{st})$ to the topologically unipotent set. We are dealing here with a *p*-adic analogue of a Green function, so we write  $Q(G, \hat{T}_{st})$  for the restriction of  $R(G, \hat{T}_{st})$  to the topologically unipotent set in  $G^F$ .

To use the reduction formula, we must establish an identity between  $Q(G, \hat{T}_{st})$  and  $Q(G', \hat{T}'_{st})$ , where  $\mathbf{G}'$  is an inner form of  $\mathbf{G}$ . To prove this identity, we use Murnaghan-Kirillov theory. The idea is to use a logarithm map and Kazhdan's proof of the Springer Hypothesis [31] to express  $Q(G, \hat{T}_{st})$  as the Fourier transform of a stable orbital integral on the Lie algebra of  $G^F$ . We then invoke a deep result of Waldspurger [63], to the effect that the fundamental lemma is valid for inner forms, and this completes the proof.

However, there are two difficulties with this argument, one pleasant, one not. The pleasant difficulty is about a certain sign in Waldspurger's result. It is given in [63] as a ratio of gamma constants. For us, it is necessary that this ratio be equal to Kottwitz' sign  $e(\mathbf{G})$  [33]. This equality of signs is a particular case of a conjecture of Kottwitz. Because of its importance, here and elsewhere, we give two proofs, the first using Shalika germs, the second continuing in the combinatorial spirit of [63].

The unpleasant difficulty is about the logarithm map, which is required to satisfy certain compatibility properties with respect to the Moy-Prasad filtrations on G and its Lie algebra. It is at this point that restrictions on k must be imposed. We require that  $p \ge (2 + e)n$ , where p is the residual characteristic of k, e is the ramification degree of  $k/\mathbb{Q}_p$ , and n is the dimension of a faithful algebraic representation of  $\mathbf{G}$  over k.

Finally, some remarks about exhaustion. All depth-zero supercuspidal representations of  $G^F$  are constructed in [44]. Many of them do not appear in our *L*-packets  $\Pi(\varphi)$ . They should appear in square-integrable *L*-packets where  $\varphi$  is tame, but has a nontrivial component on  $\operatorname{SL}_2(\mathbb{C})$  and therefore cannot be in general position. For groups with connected center, such *L*-packets have been found for unramified  $\varphi$  in [39], [40], [41], [48]. For groups with connected center, the *L*-packets constructed in this paper should be exactly those depthzero *L*-packets which consist entirely of supercuspidal representations. See Chapter 3 for more discussion of this.

We thank Robert Kottwitz, Fiona Murnaghan, Dipendra Prasad, Gopal Prasad, Loren Spice, and Jiu-Kang Yu for helpful conversations. We thank Loren Spice for allowing us to use his proof of Lemma B.7.2. Part of this work was done in 2001 while one of us (MR) was visiting the École Normale Supérieure in Paris, and the Korteweg-de Vries Institute in Amsterdam. He thanks Anne-Marie Aubert and Eric Opdam, respectively, for their hospitality. Finally, we acknowledge the National Science Foundation for its support, via grants DMS-0200542 (SD) and DMS-0207231 (MR).

While we were writing the details of our stability proof, D. Kazhdan and Y. Varshavsky announced a similar stability result, also using Murhaghan-Kirillov theory. See [32].

#### 1. Basic notation

The cardinality of a finite set X is denoted by |X|. We denote the action of a group G on a set X by  $g \cdot x$  or  $g \cdot x$ , for  $g \in G, x \in X$ . The fixed point set of g in X is denoted by  $X^g$ , and  $X^G := \bigcap_{g \in G} X^g$ . The set of G-orbits in X is denoted by X/G. The centralizer of  $g \in G$  is denoted by  $C_G(g)$ . The conjugation

801

map  $g' \mapsto gg'g^{-1}$  on G is denoted by  $\operatorname{Ad}(g)$ . The normalizer of a subgroup  $S \subset G$  is denoted by N(G, S). In this paper, the phrase "representation of a group G" means "equivalence class of complex representations of G". The set of irreducible representations of a finite group G is denoted by  $\operatorname{Irr}(G)$ .

In this paper, k is a field of characteristic zero with a nontrivial discrete valuation for which k is complete with finite residue field  $\mathfrak{f}$ . Let  $q = |\mathfrak{f}|$ , and let p be the characteristic of  $\mathfrak{f}$ . We fix an algebraic closure  $\overline{k}$  of k. Let K be the maximal unramified extension of k in  $\overline{k}$ , and let  $\mathfrak{F}$  denote the residue field of K. Then  $\mathfrak{F}$  is an algebraic closure of  $\mathfrak{f}$ . Until Section 12 there are no restrictions on p or q. We fix an element  $\varpi \in k$  of valuation equal to one.

Let  $\mathcal{I}$  be the inertia subgroup of the Galois group  $\operatorname{Gal}(k/k)$ , and let  $\Gamma = \operatorname{Gal}(\bar{k}/k)/\mathcal{I}$ . Then  $\Gamma$  is topologically generated by an element Frob whose *inverse* induces the automorphism  $x \mapsto x^q$  on  $\mathfrak{F}$ . We let Frob, "the Frobenius", denote both this automorphism of K/k and the automorphism of  $\mathfrak{F}/\mathfrak{f}$  which it induces. We have  $K = \bar{k}^{\mathcal{I}}$ ,  $k = K^{\operatorname{Frob}}$ .

We use the following conventions for algebraic groups and their groups of rational points. For any k-group **G**, we identify **G** with its group  $\mathbf{G}(\bar{k})$  of  $\bar{k}$ -rational points, and let  $G := \mathbf{G}(K) = \mathbf{G}^{\mathcal{I}}$  denote the K-rational points of **G**. For most of our purposes, the group G will play the role of "algebraic group". The given action of  $\operatorname{Gal}(\bar{k}/k)$  on **G** restricts to an action of  $\Gamma$  on G, which is completely determined by an automorphism  $F \in \operatorname{Aut}(G)$  given by the action of Frob. We have  $G^F = \mathbf{G}(k)$ . Likewise, we identify f-groups **G** with their groups of  $\mathfrak{F}$ -rational points, and we have  $\mathbf{G}^F = \mathbf{G}(\mathfrak{f})$ .

The set of irreducible admissible representations of  $G^F$  is denoted by  $\operatorname{Irr}(G^F)$ . The subset of square-integrable representations in  $\operatorname{Irr}(G^F)$  is denoted by  $\operatorname{Irr}^2(G^F)$ .

If **S** is a k-torus in **G**, we say that a character  $\theta \in \operatorname{Irr}(S^F)$  is F-regular if  $\theta$  has trivial stabilizer in  $[N(G, S)/S]^F$ .

Given an element  $\gamma$  in either **G** or **G**, we let  $\mathbf{G}_{\gamma}$  or  $\mathbf{G}_{\gamma}$  denote the *identity* component of the centralizer of  $\gamma$  in **G** or **G**, respectively. If  $\gamma \in G$ , then we set  $G_{\gamma} := G \cap \mathbf{G}_{\gamma}$ . We say the element  $\gamma$  in **G** or **G** is regular semisimple if  $\mathbf{G}_{\gamma}$ or  $\mathbf{G}_{\gamma}$  is a torus. We let  $G^{rss}$  denote the set of regular semisimple elements of G. We say that  $\gamma$  in **G** or **G** is strongly regular semisimple if  $C_{\mathbf{G}}(\gamma)$  or  $C_{\mathbf{G}}(\gamma)$ is a torus. We let  $G^{srss}$  denote the set of strongly regular semisimple elements of G. If **S** is a maximal k-torus in **G**, then by [8, 1.10] the set  $G^{srss} \cap S^F$  is nonempty.

For two reductive groups  $\mathbf{G}_1$ ,  $\mathbf{G}_2$  or  $\mathbf{G}_1$ ,  $\mathbf{G}_2$  of respective ranks  $r_1, r_2$  over k or  $\mathfrak{f}$ , we let

$$\varepsilon(\mathbf{G}_1, \mathbf{G}_2) = (-1)^{r_1 - r_2}, \qquad \varepsilon(\mathbf{G}_1, \mathbf{G}_2) = (-1)^{r_1 - r_2},$$

respectively.

For any torus **S** or **S**, we let  $X_*(\mathbf{S})$  or  $X_*(\mathbf{S})$  denote the group of algebraic one-parameter subgroups of **S** or **S**. We say an f-torus  $S \subset G$  is *F*-minisotropic in **G** if every  $\mu \in X_*(\mathbf{S})^F$  has image contained in the center of **G**.

The analogous notion for tori in **G** has an extra condition: In this paper, an *unramified torus* is a group of the form  $S = \mathbf{S}(K)$ , where **S** is a k-torus which splits over K. These conditions mean that  $\mathcal{I}$  acts trivially on  $X_*(\mathbf{S})$ , and the action of  $\operatorname{Gal}(\overline{k}/k)$  on  $X_*(\mathbf{S})$  factors through  $\Gamma$ . An *F*-minisotropic torus in G is a group of the form  $S = \mathbf{S}(K)$ , where **S** is a k-torus in **G** such that **S** is split over K, and the Frobenius F, arising from the given k-structure on **G**, has the property that every  $\mu \in X_*(\mathbf{S})^F$  has image contained in the center of **G**.

If **S** is a K-split k-torus, we let  ${}^{0}S$  denote the maximal bounded subgroup of the unramified torus S. We have an isomorphism

$$K^{\times} \otimes X_*(\mathbf{S}) \xrightarrow{\sim} S$$

given by evaluation. This restricts to an isomorphism

$$R_K^{\times} \otimes X_*(\mathbf{S}) \xrightarrow{\sim} {}^0S_*$$

where  $R_K^{\times}$  is the group of units in the ring of integers of K.

For this paper, until the appendices, **G** denotes a connected reductive k-group which splits over K. Let F be the Frobenius automorphism of G arising from the given k-structure on **G**. Let  $\mathcal{B}(G)$ ,  $\mathcal{B}(G^F)$  denote the Bruhat-Tits buildings of G,  $G^F$ , respectively. The Frobenius F acts naturally on  $\mathcal{B}(G)$ , and we have  $\mathcal{B}(G^F) = \mathcal{B}(G)^F$ .

Let  $j : \mathbf{G} \to \mathbf{G}_{ad}$  denote the adjoint quotient. Following our conventions, we set  $G_{ad} := \mathbf{G}_{ad}(K)$ , and denote again by F the action of Frob on  $G_{ad}$ .

Via the map j, the group G acts on  $\mathcal{B}(G_{ad})$ . The latter is sometimes referred to as the "reduced building" of G. Likewise, the reduced building of  $G^F$  is  $\mathcal{B}(G^F_{ad}) = \mathcal{B}(G_{ad})^F$ .

Each unramified torus S in G determines apartments  $\mathcal{A}(S) \subset \mathcal{B}(G)$  and  $\mathcal{A}_{ad}(S) \subset \mathcal{B}(G_{ad})$ ; these apartments can be defined as the fixed-point sets of  ${}^{0}S$  in  $\mathcal{B}(G)$  and  $\mathcal{B}(G_{ad})$ , respectively. The Euclidean closure of any subset J of an apartment is denoted by  $\overline{J}$ .

If J is an F-stable subset of a facet in  $\mathcal{B}(G)$  or  $\mathcal{B}(G_{ad})$ , we let  $G_J$  denote the corresponding parahoric subgroup of G, and let  $G_J^+$  denote the pro-unipotent radical of  $G_J$ . The quotient  $\mathsf{G}_J := G_J/G_J^+$  is the group of  $\mathfrak{F}$ -points of a connected reductive group over  $\mathfrak{f}$ . We have  $F(G_J) = G_J, F(G_J^+) = G_J^+$ , and the induced action of F on  $\mathsf{G}_J$  agrees with the  $\mathfrak{f}$ -structure on  $\mathsf{G}_J$ . We have  $\mathsf{G}_J^F = G_J^F/G_J^{+F}$ .

Recall that **G** is split over K. By [10, 5.1.10], there exists a K-split maximal torus  $\mathbf{T} \subset \mathbf{G}$  which is defined over k and maximally k-split. We abbreviate  $X := X_*(\mathbf{T}), \ \mathcal{A} := \mathcal{A}(T)$ . Let N be the normalizer of T in G. The

affine Weyl group of T in G is the quotient

$$W := N/^0 T.$$

We will use  $T = \mathbf{T}(K)$  as a "platonic" unramified torus in G; various unramified tori S as above will arise from twisted embeddings of T in G.

Let  $\mathbf{T}_{ad} = j(\mathbf{T})$  denote the image of  $\mathbf{T}$  in  $\mathbf{G}_{ad}$ , and abbreviate  $\mathcal{A}_{ad} := \mathcal{A}(T_{ad}), X_{ad} := X_*(\mathbf{T}_{ad})$ . Let  $W_{ad}$  be the affine Weyl group of  $T_{ad}$  in  $G_{ad}$ . Since  $\mathbf{T}$  and  $\mathbf{T}_{ad}$  are defined over k, the Frobenius F induces automorphisms of  $X, X_{ad}, \mathcal{A}, \mathcal{A}_{ad}, W, W_{ad}$ . We write also

$$j: X \to X_{\mathrm{ad}}, \quad j: W \longrightarrow W_{\mathrm{ad}}$$

for the maps induced by j. These maps are F-equivariant, since j is defined over k. The kernel and image of the latter map are given as follows.

We may identify X with the normal subgroup  $T/{}^{0}T \triangleleft W$ , via evaluation at  $\varpi$ . If  $\lambda \in X$ , we let  $t_{\lambda} := \lambda(\varpi)$  denote both the corresponding element of T and its image in W. There is a map  $W_{\rm ad} \longrightarrow X_{\rm ad}/jX$ , to be defined shortly, which fits into an exact sequence

(3) 
$$1 \longrightarrow X^W \longrightarrow W \xrightarrow{j} W_{ad} \longrightarrow X_{ad}/jX \longrightarrow 1.$$

Note that the last group  $X_{\rm ad}/jX$  is finite. The group  $X^W$  acts trivially on  $\mathcal{A}_{\rm ad}$ .

There exists an *F*-stable alcove  $C \subset \mathcal{A}$ . Let  $W^{\circ}$  be the subgroup of Wgenerated by reflections in the walls of C, and let  $\Omega_C := \{\omega \in W : \omega \cdot C = C\}$ . The group  $\Omega_C$  is abelian, isomorphic to the quotient of X by the co-root sublattice  $X^{\circ} \subset X$ . The normal subgroup  $W^{\circ} \triangleleft W$  acts simply-transitively on alcoves in  $\mathcal{A}$ , so we have a semidirect product expression

$$W = \Omega_C W^\circ$$

A similar discussion and decomposition holds for  $W_{\rm ad}$ .

We have been using F to denote the Frobenius arising from an arbitrary K-split k-structure on G. When this k-structure is in fact k-quasi-split, we denote the Frobenius by F. The key difference in the quasi-split case is the existence of an F-fixed hyperspecial vertex  $o \in \mathcal{A}_{ad}$ .

In the quasi-split case, we denote by  $\vartheta$  the automorphisms of  $X, X_{ad}, \mathcal{A}$ ,  $\mathcal{A}_{ad}, W, W_{ad}$  induced by F. Choose a  $\vartheta$ -fixed hyperspecial vertex  $o \in \mathcal{A}_{ad}$ . We let  $W_o$  be the image of  $N_o := N \cap G_o$  in W. We may identify  $W_o = N/T$  via the natural maps

$$W_o \hookrightarrow W = N/{}^0T \longrightarrow N/T.$$

The map j is injective on  $W_o$  and we identify  $W_o$  with  $j(W_o)$ . We have semidirect product decompositions

$$W = X \rtimes W_o, \qquad W_{\mathrm{ad}} = X_{\mathrm{ad}} \rtimes W_o,$$

and all factors are preserved by  $\vartheta$ . The map  $W_{\rm ad} \longrightarrow X_{\rm ad}/jX$  in the exact sequence (3) is induced by projection onto the  $X_{\rm ad}$  factor in  $W_{\rm ad}$ .

Finally, an inner twist of F by a cocycle  $u \in Z^1(F, G)$  (see §2) will be denoted by  $F_u := \operatorname{Ad}(u) \circ F$ .

#### 2. Remarks on Galois cohomology

To state the Langlands conjectures at the level of refinement considered in this paper requires some notions from the Galois cohomology of reductive groups over local fields. The central results here are due to Kottwitz [34], [35], who computes  $H^1(k, \mathbf{G})$  in terms of the action of  $\operatorname{Gal}(\bar{k}/k)$  on the center of the dual group of  $\mathbf{G}$ , and Bruhat-Tits [11], who compute  $H^1(k, \mathbf{G})$  in terms of the building of G. Here we give simple proofs of the above-mentioned results at the level of cocycles. This allows us to construct cocycles in  $\mathbf{G}$  from fixed-points in  $\mathcal{A}$  of elements in the affine Weyl group. Such fixed-points arise from the Langlands parameters we consider. Thus we can associate an explicit Frobenius to each Langlands parameter. We also use our cocycles to give representatives for various stable and rational classes of tori and semisimple elements in G. These will be used in the proof of stability.

2.1. Unramified cohomology. Let U be a group and let F be an endomorphism of U. For an integer  $d \ge 1$  and  $g \in U$ , define

$$N_d(F)(g) := gF(g) \cdots F^{d-1}(g) \in U.$$

Note that

(4) 
$$N_{dm}(F) = N_m(F^d) \circ N_d(F).$$

Assume that every element of U is fixed by some power of F. Giving U the discrete topology, this means that the group  $\hat{\mathbb{Z}}$  of profinite integers, with topological generator F, acts continuously on U. We denote by

$$H^1(F,U) = H^1(\hat{\mathbb{Z}},U)$$

the continuous (nonabelian) cohomology of U. Any cocycle is determined by its value on F, which is an element of the set

$$Z^{1}(F,U) := \{ u \in U : N_{m}(u) = 1 \text{ for some } m \ge 1 \}.$$

Thus we view cocycles as elements of U, and  $H^1(F, U)$  is the quotient of  $Z^1(F, U)$  under the U-action:  $g * u = guF(g)^{-1}$ . Note that if  $N_m(u) = 1$  and  $F^d(g) = g$ , then  $N_{md}(F)(g * u) = 1$ .

If U is nonabelian, the set  $Z^1(F, U)$  of cocycles is not closed under multiplication. However, if  $u, v \in Z^1(F, U)$  and  $d \ge 1$  we have

(5) 
$$N_d(F)(vu) = N_d(F_u)(v) \cdot N_d(F)(u),$$

where

$$F_u := \operatorname{Ad}(u) \circ F \in \operatorname{End}(U).$$

From Equations (4) and (5) we conclude:

LEMMA 2.1.1. If two of the following hold, then so does the third:

- $(1) \ u \in Z^1(F,U),$
- (2)  $v \in Z^1(F_u, U),$
- $(3) \ vu \in Z^1(F,U).$

LEMMA 2.1.2. If the fixed-point group  $U^{F^d}$  is finite for each  $d \ge 1$ , then  $Z^1(F,U) = U$ .

*Proof.* Fix  $d \ge 1$  and suppose that  $g^m = 1$  for each  $g \in U^{F^d}$ . From Equation (4), we have

$$N_{dm}(F)(g) = N_m(F^d) \left( N_d(F)(g) \right) = \left( N_d(F)(g) \right)^m = 1.$$

LEMMA 2.1.3. Suppose U is a compact group with endomorphism F and a decreasing filtration  $U = U_0 \supset U_1 \supset U_2 \supset \cdots$  by open normal F-stable subgroups  $U_n$  such that  $\bigcap_n U_n = \{1\}$ . Assume that  $H^1(F, U_n/U_{n+1}) = 1$  for all  $n \ge 0$ . Then  $H^1(F, U) = 1$ .

*Proof.* Let  $u \in Z^1(F, U)$ , so that  $u \in U_n$  for some  $n \ge 0$ . By the vanishing assumption and normality, there are  $g_0 \in U_n$  and  $u_1 \in U_{n+1}$  such that  $u = g_0 * u_1$ . Then  $u_1 = g_0^{-1} * u \in Z^1(F, U)$ . Repeating, we have elements  $g_k, u_k \in U_{n+k}$  for all  $k \ge 1$ , such that  $u = (g_0g_1\cdots g_{k-1}) * u_k$ . Since U is compact, the limit  $g := \lim_k g_0g_1\cdots g_k$  exists, and u = g \* 1.

2.2. Steinberg's vanishing theorem. In this section, **G** is only required to be a connected k-group, with Frobenius automorphism F on G. At several points we use the following consequence of a well-known result of Steinberg [56, Thm. 1.9]:

THEOREM 2.2.1.  $H^1(K, \mathbf{G}) = 1$ .

One consequence of Theorem 2.2.1 is that the natural surjection  $\operatorname{Gal}(\bar{k}/k) \to \Gamma$ induces an isomorphism

$$H^1(F,G) \simeq H^1(k,\mathbf{G}).$$

Each cocycle  $u \in Z^1(F, G)$  arises from a twisted k-structure on **G**, under which Frob acts on G via the automorphism

$$F_u := \operatorname{Ad}(u) \circ F \in \operatorname{Aut}(G),$$

so that  $G^{F_u}$  is the group of k-rational points under this twisted k-structure [51, III.1.3]. Note that for  $g \in G$ , we have

$$\operatorname{Ad}(g) \circ F_u = \operatorname{F}_{g \ast u} \circ \operatorname{Ad}(g),$$

so that Ad(g) induces an isomorphism

$$\operatorname{Ad}(g): G^{F_u} \xrightarrow{\sim} G^{F_{g*u}}.$$

Thus, the isomorphism class of  $G^{F_u}$  depends only on the class of u in  $H^1(F, G)$ . However, the dependence is noncanonical, in the sense that a class in  $H^1(F, G)$ does not determine a unique twist of F; one must choose a cocycle in the class. We must therefore accept a wide range of Frobenius endomorphisms  $F_u$  giving rise to the same k-isomorphism class of groups.

2.3. Explicit cocycles. For the rest of this chapter, **G** is a connected reductive k-group with Frobenius automorphism F on G. To keep things as simple and clear as possible, we assume that **G** is K-split and k-quasi-split, even though these assumptions are not necessary until later in the paper. The following result is a special case of [64, Prop. 2.3]. We give a direct proof, in our context.

LEMMA 2.3.1. For each  $x \in \mathcal{B}(G)^F$  we have  $H^1(F, G_x) = 1$ , where  $G_x$  is the parahoric subgroup attached to x.

*Proof.* If  $u \in Z^1(F, G_x)$ , then  $u \in G_x^{F^d}$  for some  $d \ge 1$ . We want to apply 2.1.3 to the compact group  $U = G_x^{F^d}$ . Let  $G_{x,r}, r \in \mathbb{R}_{\ge 0}$ , be the Moy-Prasad-Yu filtration of  $G_x$  [65]. There is an increasing sequence  $\{r_n : n = 0, 1, 2, \ldots\} \subset \mathbb{R}_{\ge 0}$  such that for every  $r \ge 0$  we have  $G_{x,r} = G_{x,r_n}$  for a unique n. These filtration subgroups are F-stable; we set  $U_n := G_{x,r_n}^{F^d}$ .

Each quotient group  $U_n/U_{n+1}$  is the group of  $\mathfrak{f}_d$ -rational points in a connected  $\mathfrak{f}$ -group  $\mathsf{U}_n$ . Here  $\mathfrak{f}_d$  denotes the degree d extension of  $\mathfrak{f}$ . By the Lang-Steinberg theorem, we have  $H^1(\mathfrak{f}, \mathsf{U}_n) = 1$  for all  $n \geq 0$ . Since the natural map

$$H^1(\mathfrak{f}_d/\mathfrak{f}, \mathsf{U}_n(\mathfrak{f}_d)) \longrightarrow H^1(\mathfrak{f}, \mathsf{U}_n)$$

is injective [51, I.5.8], we have  $H^1(\mathfrak{f}_d/\mathfrak{f}, \mathsf{U}_n(\mathfrak{f}_d)) = 1$  for all  $n \geq 0$ .

We have shown that the groups  $U_n$  satisfy the conditions of Lemma 2.1.3, which implies that the cocycle u is a coboundary in  $H^1(F, U_0)$ , hence also in  $H^1(F, G_x)$ .

Recall that **T** is a K-split maximal k-torus in **G**, such that **T** contains a maximal k-split torus in **G**, and N is the normalizer of T in G. The affine Weyl group of T in G is the quotient  $W := N/{}^{0}T$ , where  ${}^{0}T$  is the maximal bounded subgroup of T. The apartment of T in  $\mathcal{B}(G)$  is denoted by  $\mathcal{A}$ , and the N-action on  $\mathcal{A}$  factors through a faithful action of W on  $\mathcal{A}$ . To describe  $H^1(\mathbf{F}, G)$  on the level of cocycles, the first step is to reduce the group in which the cocycles live. Let C be an  $\mathbf{F}$ -stable alcove in  $\mathcal{A}$  (see [60, 3.4.3]). Let  $G_C$  be the Iwahori subgroup of G attached to C. The normalizer in G of  $G_C$  is the group

$$G_C^\star := \{ g \in G : g \cdot C = C \}.$$

We have  $N \cap G_C = {}^0T$ , and we set

$$N_C := N \cap G_C^\star.$$

Then the group

$$\Omega_C := \{ \omega \in W : \ \omega \cdot C = C \}$$

is the image of  $N_C$  in W. The inclusion  $N_C \hookrightarrow G_C^{\star}$  induces an isomorphism

$$d: \Omega_C \xrightarrow{\sim} G_C^{\star}/G_C.$$

Since  $\mathbf{F} \cdot C = C$ , we have  $\mathbf{F}(G_C^{\star}) = G_C^{\star}$ , so we may define  $H^1(\mathbf{F}, G_C^{\star})$  as in 2.2, and similarly for  $H^1(\mathbf{F}, N_C)$ . The first reduction relies on the existence and conjugacy of rational alcoves, already used above.

LEMMA 2.3.2. The inclusion  $G_C^{\star} \hookrightarrow G$  induces an isomorphism

$$H^1(\mathbf{F}, G_C^{\star}) \xrightarrow{\sim} H^1(\mathbf{F}, G).$$

*Proof.* We first prove surjectivity. Let  $u \in Z^1(\mathbf{F}, G)$ . By [60, 1.10.3] there is an  $\mathbf{F}_u$ -stable alcove  $C_u \subset \mathcal{B}(G)$  and  $g \cdot C_u = C$  for some  $g \in G$ . Since  $\mathbf{F}_u \cdot C_u = C_u$ , we have  $u \mathbf{F}(g^{-1}) \cdot C = g^{-1} \cdot C$ , i.e.,  $g * u \in G_C^*$ .

For injectivity, suppose  $u, v \in Z^1(\mathbf{F}, G_C^{\star})$ , and g \* u = v for some  $g \in G$ . Then

$$\mathbf{F}_v \cdot g \cdot C = v \, \mathbf{F}(g) \cdot C = g u \cdot C = g \cdot C.$$

Thus  $g \cdot C$  and C are two  $F_v$ -stable alcoves in  $\mathcal{B}(G)$ . By [60, §2.5] there is  $h \in G^{F_v}$  such that  $hg \cdot C = C$ , so that  $hg \in G_C^{\star}$ . However,  $h = F_v(h)$  implies

$$(hg)u \operatorname{F}(hg)^{-1} = hv \operatorname{F}(h)^{-1} = v,$$

and so [u] = [v] in  $H^1(\mathbf{F}, G_C^{\star})$ .

To go further, we need another vanishing result. The image of  ${}^{0}T$  in  $\mathsf{G}_{C}$  is a maximal f-torus T in  $\mathsf{G}_{C}$ . We let  ${}^{0}T^{+}$  be the kernel of the natural map  ${}^{0}T \longrightarrow \mathsf{T}$ . Then  ${}^{0}T^{+}$  is the pro-unipotent radical of  ${}^{0}T$ .

Recall that  $\Gamma = \text{Gal}(K/k)$ . A topological  $\Gamma$ -module [50, XIII, p.188] is a  $\Gamma$ -module in which every element is fixed by some power of Frob.

LEMMA 2.3.3. For any  $n \in N$ , letting Frob act on  ${}^{0}T$  via  $F_{n} := Ad(n) \circ F$ makes  ${}^{0}T$  a topological  $\Gamma$ -module for which  $H^{2}(F_{n}, {}^{0}T) = 0$ .

*Proof.* As endomorphisms of T, we have  $F_n = F_w$ , where w is the image of n in N/T. Now

$$\mathbf{F}_w^k = \mathrm{Ad}[w \, \mathbf{F}(w) \cdots \mathbf{F}^{k-1}(w)] \circ \mathbf{F}^k, \text{ for all } k \ge 1.$$

Since N/T is finite, the term in brackets is 1 for some k (cf. Lemma 2.1.2) and multiples thereof. Also every  $t \in T$  is fixed by some  $F^m$  and multiples thereof. The first assertion now follows.

The exact sequence of topological  $\Gamma$ -modules

 $1 \longrightarrow {}^0T^+ \longrightarrow {}^0T \longrightarrow \mathsf{T} \longrightarrow 1$ 

gives an exact sequence [51, §2.2, p.10] in Galois cohomology:

$$\cdots \longrightarrow H^2(\mathbf{F}_w, {}^0T^+) \longrightarrow H^2(\mathbf{F}_w, {}^0T) \longrightarrow H^2(\mathbf{F}_w, \mathsf{T}) \longrightarrow \cdots$$

Since T is a torsion group,  $H^2(\mathbf{F}_w, \mathsf{T}) = 0$  by [50, Prop. 2, p.189]. Since  ${}^0T^+$  is the union of an inverse limit of torsion groups, from [50, Lemma 3, p.185] we have  $H^2(\mathbf{F}_w, {}^0T^+) = 0$ .

Consider now the following commutative diagram, where the horizontal maps are inclusions, and the vertical maps are the natural projections.

LEMMA 2.3.4. The maps a, b, c, d in the above diagram induce isomorphisms  $a_*, b_*, c_*, d_*$  on  $H^1(\mathbf{F}, \cdot)$ .

*Proof.* The map d is already an isomorphism. The map  $a_*$  is surjective by Lemma 2.3.3 and [51, Cor., p. 54]. Since the induced diagram on cohomology is commutative, the map  $c_*$  is also surjective.

If  $u \in Z^1(\mathbf{F}, G_C^{\star})$ , then from [51, Cors. 1 and 2, p. 52] the fiber of  $c_*$  through [u] is in bijection with  $\ker[H^1(\mathbf{F}_u, G_C^{\star}) \to H^1(\mathbf{F}_u, G_C^{\star}/G_C)]$ . By the exact sequence

$$\cdots \longrightarrow H^1(\mathbf{F}_u, G_C) \longrightarrow H^1(\mathbf{F}_u, G_C^{\star}) \longrightarrow H^1(\mathbf{F}_u, G_C^{\star}/G_C)$$

in nonabelian cohomology [51, Prop. 38, p.51] and the vanishing of  $H^1(\mathbf{F}_u, G_C)$  by Lemma 2.3.1, the above kernel is trivial. Hence  $c_*$  is injective. A similar argument shows that  $a_*$  is injective, which completes the proof.

2.4. *Kottwitz' theorem.* In this section we will recover Kottwitz' theorem on the level of cocycles. First we need an elementary result.

LEMMA 2.4.1. Let A be a finitely generated abelian group, and let  $\sigma \in Aut(A)$  be an automorphism of finite order. Define

$$A_1 := \{ a \in A : (1 + \sigma + \dots + \sigma^{n-1}) a = 0 \quad \text{for some} \quad n \ge 1 \},$$
$$A_2 := \{ a \in A : ma \in (1 - \sigma) A \quad \text{for some} \quad m \ge 1 \}.$$

*Then*  $A_1 = A_2$ *.* 

Proof. For 
$$p \ge 1$$
 let  $N_p = 1 + \sigma + \dots + \sigma^{p-1} \in \text{End}(A)$ . Then  
 $N_{pq} = N_p + \sigma^p N_p + \dots + \sigma^{p(q-1)} N_p = (1 + \sigma^p + \dots + \sigma^{p(q-1)}) N_p$ 

Hence if  $N_p(a) = N_q(b) = 0$ , then  $N_{pq}(a+b) = 0$ . That is,  $A_1$  is a subgroup of A. Also, since  $A_{tor}$  is finite, every element of  $A_{tor}$  is fixed by some power of  $\sigma$ . If qa = 0, then  $\sigma^p(a) = a$  for some  $p \ge 1$ , so that  $N_{pq}(a) = qN_p(a) = N_p(qa) = 0$ . Thus,  $A_{tor} \subseteq A_1$ .

Set  $\overline{A} = A_1/A_{\text{tor}}$ ,  $V = \mathbb{Q} \otimes \overline{A}$ . The latter is a finite-dimensional  $\mathbb{Q}$ -vector space, to which  $\sigma$  and  $N_p$  extend for all p. We claim that  $V^{\sigma} = \{0\}$ . If  $0 \neq v \in V^{\sigma}$ , we may assume, by clearing denominators, that  $v \in \overline{A}$ . Then  $N_p(v) = pv \neq 0$  for all  $p \geq 1$ , a contradiction. Hence  $1 - \sigma$  is invertible on V. Let  $a \in A_1$  have image  $\overline{a} \in \overline{A}$ . Write  $\overline{a} = (1 - \sigma)\overline{b}$ , for some  $\overline{b} \in V$ . Clearing denominators, we have  $m\overline{a} = (1 - \sigma)\overline{c}$  for some  $m \in \mathbb{Z}$ ,  $c \in A_1$ . So  $ma = (1 - \sigma)c + z$ , where  $z \in A_{\text{tor}}$ . Say qz = 0. Then  $qma = (1 - \sigma)qc \in (1 - \sigma)A$ , showing that  $A_1 \subseteq A_2$ .

The other containment is easy: If  $qa = (1 - \sigma)b$ , and p is the order of  $\sigma$ , then

$$N_{pq}(a) = qN_p(a) = N_p(qa) = N_p(1-\sigma)b = (1-\sigma^p)b = 0.$$

Let  $X = X_*(\mathbf{T})$ , and let  $W^\circ$  be the subgroup of W generated by reflections in the walls of an alcove in  $\mathcal{A}$ . Evaluation at  $\varpi$  identifies  $\lambda \in X$  with the operator  $t_{\lambda} \in W$  of translation by  $\lambda$  on  $\mathcal{A}$ . Under this identification,  $X \cap W^\circ =$ :  $X^\circ$  is the co-root lattice of  $\mathbf{T}$ . We set  $\overline{X} := X/X^\circ$ . The group  $W^\circ$  acts simplytransitively on alcoves, hence we have the semidirect product decomposition

$$W = W^{\circ} \rtimes \Omega_C.$$

The automorphism F preserves T, hence induces an automorphism  $\vartheta$  of W, which preserves  $X, W^{\circ}, \Omega_{C}$ . If **G** is actually k-split then  $\vartheta$  is trivial. In general,  $\vartheta$  has finite order.

For  $\lambda \in X$ , let  $\omega_{\lambda}$  be the unique element of  $t_{\lambda}W^{\circ} \cap \Omega_{C}$ . Then  $\omega_{\lambda} = 1$  exactly when  $\lambda$  belongs to  $X^{\circ}$ ; the map  $\lambda \mapsto \omega_{\lambda}$  induces a  $\vartheta$ -equivariant group isomorphism  $\bar{X} \xrightarrow{\sim} \Omega_{C}$ .

COROLLARY 2.4.2. The map  $\lambda \mapsto \omega_{\lambda}$  induces an isomorphism

$$[\bar{X}/(1-\vartheta)\bar{X}]_{\text{tor}} \xrightarrow{\sim} H^1(\mathbf{F},\Omega_C).$$

*Proof.* Apply Lemma 2.4.1 to the abelian group  $A = \Omega_C$ ,  $\sigma = \vartheta$ . Since  $(1 - \vartheta)\Omega_C \subset (\Omega_C)_2$ , we have

$$H^{1}(\mathbf{F},\Omega_{C}) = (\Omega_{C})_{1}/(1-\vartheta)\Omega_{C} = (\Omega_{C})_{2}/(1-\vartheta)\Omega_{C} = [\Omega_{C}/(1-\vartheta)\Omega_{C}]_{\text{tor}}.$$

The isomorphism  $\bar{X} \simeq \Omega_C$  finishes the proof.

Combining 2.3.4 and 2.4.2, we can express Kottwitz' isomorphism in the following form.

COROLLARY 2.4.3. The composition

$$[\bar{X}/(1-\vartheta)\bar{X}]_{\text{tor}} \xrightarrow{\sim} H^1(\mathcal{F},\Omega_C) \xrightarrow{a_*^{-1}} H^1(\mathcal{F},N_C) \xrightarrow{b_*} H^1(\mathcal{F},G)$$

is a bijection. A class  $[\lambda] \in [\bar{X}/(1-\vartheta)\bar{X}]_{tor}$ , represented by  $\lambda \in X$ , corresponds to the class  $[\dot{\omega}_{\lambda}] \in H^1(\mathbf{F}, G)$ , where  $\dot{\omega}_{\lambda} \in Z^1(\mathbf{F}, N_C)$  is any element whose image in W is the unique element  $\omega_{\lambda}$  of  $t_{\lambda}W^{\circ} \cap \Omega_C$ .

2.5. The dual group. Corollary 2.4.3 is usually expressed in terms of the dual group  $\hat{G}$  of **G**. Let  $Y := X^*(\mathbf{T})$  be the algebraic character group of **T**, and let  $\langle , \rangle : X \times Y \to \mathbb{Z}$  be the natural pairing. The dual group of **T** is the complex torus  $\hat{T} := Y \otimes \mathbb{C}^{\times}$ ; it is a maximal torus in  $\hat{G}$ . Let  $\hat{Z}$  denote the center of  $\hat{G}$ .

For any  $\sigma \in \operatorname{Aut}(X)$ , let  $\hat{\sigma} \in \operatorname{Aut}(Y)$  be defined by

$$\langle \sigma \lambda, \eta \rangle = \langle \lambda, \hat{\sigma} \eta \rangle, \qquad \lambda \in X, \ \eta \in Y.$$

The action of  $\hat{\vartheta}$  on Y extends to the automorphism  $\hat{\vartheta} \otimes 1$  of  $\hat{T}$ , thence by restriction to an automorphism of  $\hat{Z}$ .

We may identify

$$\bar{X} = \operatorname{Hom}(\hat{Z}, \mathbb{C}^{\times}),$$

via restriction of characters. Restricting further to  $\hat{Z}^{\hat{\vartheta}}$ , we may identify

$$\bar{X}/(1-\vartheta)\bar{X} = \operatorname{Hom}(\hat{Z}^\vartheta, \mathbb{C}^{\times}).$$

The elements in  $\bar{X}/(1-\vartheta)\bar{X}$  vanishing on the identity component of  $\hat{Z}^{\hat{\vartheta}}$  are exactly the torsion elements in  $\bar{X}/(1-\vartheta)\bar{X}$ . Hence we may identify

$$[\bar{X}/(1-\vartheta)\bar{X}]_{\text{tor}} = \text{Irr}[\pi_0(\hat{Z}^\vartheta)].$$

With these identifications, Corollary 2.4.3 becomes the usual expression of Kottwitz' isomorphism.

2.6. A commutative diagram. It is at this point that we first use seriously the assumption that F arises from a quasi-split k-structure on **G** which is K-split. Such an assumption ensures the existence of an F-fixed hyperspecial vertex  $o \in j(\bar{C})$ .

811

Let  $W_o$  be the image of  $N_o = N \cap G_o$  in W. The latter has another semidirect product expression

$$W = X \rtimes W_o,$$

and both factors are preserved by  $\vartheta$ .

Since **G** is K-split and k-quasi-split, there is a  $\operatorname{Gal}(\overline{k}/k)$ -invariant pinning in G. Applying Proposition 3 of [59] to this pinning, we see that there is an F-stable finite subgroup  $\dot{W}_o \subset N_o$  projecting onto  $W_o$ .

Let  $w \in W_o$ , choose a lift  $\dot{w} \in \dot{W}_o$  of w, and set  $F_w := \operatorname{Ad}(\dot{w}) \circ F$ . Applying Lemmas 2.1.2 and 2.3.1 to the groups  $\dot{W}_o$  and  $G_o$ , respectively, there exists  $p_0 \in G_o$  such that

$$\dot{w} = p_0^{-1} \operatorname{F}(p_0).$$

The map  $\operatorname{Ad}(p_0): T \longrightarrow G$  intertwines the pairs  $(T, F_w), (G, F)$ . Let

(6) 
$$r: H^1(\mathbf{F}_w, T) \longrightarrow H^1(\mathbf{F}, G),$$

be the map induced by  $\operatorname{Ad}(p_0)$ .

A version of the following result was proved by Kottwitz [35, Thm. 1.2].

LEMMA 2.6.1. We have a commutative diagram  $[X/(1-w\vartheta)X]_{tor} \longrightarrow [\bar{X}/(1-\vartheta)\bar{X}]_{tor}$   $\simeq \downarrow \qquad \qquad \downarrow \simeq$  $H^1(\mathbf{F}_w,T) \xrightarrow{r} H^1(\mathbf{F},G)$ 

where the vertical maps are from 2.4.3 applied to T and G, the top row is the natural projection and the map r is defined as in Equation (6).

*Proof.* Starting at  $[X/(1 - w\vartheta)X]_{tor}$  and going down the left side, then over on the bottom row, we see that the class of  $\lambda \in [X/(1 - w\vartheta)X]_{tor}$  goes to the class

$$[p_0 t_{\lambda} p_0^{-1}] = [t_{\lambda} p_0^{-1} \operatorname{F}(p_0)] = [t_{\lambda} \dot{w}] \in H^1(\operatorname{F}, G).$$

Equation (9) below shows that  $[t_{\lambda}\dot{w}] = [\dot{\omega}_{\lambda}]$ , which is the result of the other route, by Corollary 2.4.3.

2.7. Fixed points and cocycles. We continue in the set-up of Section 2.4. In this section we show how cocycles in  $Z^1(\mathbf{F}, G)$  arise from fixed-points in  $\mathcal{A}$  of elements in the affine Weyl group W. This will be used to associate Frobenius endomorphisms on G to Langlands parameters in  ${}^LG$ .

Let  $w \in W_o$ , and let  $X_w$  be the preimage in X of  $[X/(1-w\vartheta)X]_{tor}$ . For  $\lambda \in X_w$ , we define

$$\sigma_{\lambda} := t_{\lambda} w \vartheta \in W \rtimes \langle \vartheta \rangle.$$

LEMMA 2.7.1. The element  $\sigma_{\lambda} \in W \rtimes \langle \vartheta \rangle$  has finite order.

*Proof.* The element  $w\vartheta$  has finite order, say n, since it belongs to the finite group  $W_o \rtimes \langle \vartheta \rangle$ . We let  $N_{w\vartheta} = 1 + w\vartheta + \cdots + (w\vartheta)^{n-1} \in \text{End}(X)$  be the associated norm mapping. Since  $\lambda \in X_w$ , there is  $m \ge 1$  such that  $m\lambda = (1 - w\vartheta)\nu$ , for some  $\nu \in X$ . Then

$$\sigma_{\lambda}^{nm} = N_{w\vartheta}(t_{m\lambda}) = N_{w\vartheta}(1 - w\vartheta)(t_{\nu}) = 1.$$

By Lemma 2.7.1,  $\sigma_{\lambda}$  preserves a facet  $J_{\lambda}$  in  $\mathcal{A}$ . Choose an alcove  $C_{\lambda}$ in  $\mathcal{A}$  containing  $J_{\lambda}$  in its closure. Let  $W_{\lambda}$  be the subgroup of  $W^{\circ}$  generated by reflections in the hyperplanes containing  $J_{\lambda}$ . The group  $W_{\lambda}$  acts simplytransitively on alcoves in  $\mathcal{A}$  containing  $J_{\lambda}$  in their closure. Hence there is a unique element  $w_{\lambda} \in W_{\lambda}$  such that

$$\sigma_{\lambda} \cdot C_{\lambda} = w_{\lambda} \cdot C_{\lambda}.$$

Set  $y_{\lambda} := w_{\lambda}^{-1} t_{\lambda} w$ . Thus we have two expressions for  $\sigma_{\lambda}$ :

(7) 
$$t_{\lambda}w\vartheta = \sigma_{\lambda} = w_{\lambda}y_{\lambda}\vartheta,$$

and the latter is characterized as the unique factorization of  $\sigma_{\lambda}$  such that  $w_{\lambda} \in W_{\lambda}$  and  $y_{\lambda} \in W$  satisfies  $y_{\lambda}\vartheta \cdot C_{\lambda} = C_{\lambda}$ . Since  $w_{\lambda}$  fixes  $J_{\lambda}$  pointwise, we also have  $y_{\lambda}\vartheta \cdot J_{\lambda} = J_{\lambda}$ ; indeed,  $\sigma_{\lambda}$  and  $y_{\lambda}\vartheta$  have the same action on  $J_{\lambda}$ .

To briefly look ahead: Equation (7) is the essence of our Langlands correspondence. The expression  $t_{\lambda}w\vartheta$  will arise from a certain kind of Langlands parameter; that is,  $t_{\lambda}w\vartheta$  is an object on the "geometric side". On the other hand,  $y_{\lambda}$  and  $w_{\lambda}$  will determine a twisted Frobenius  $F_{\lambda}$  and an unramified torus in  $G^{F_{\lambda}}$ , respectively, so  $y_{\lambda}$  and  $w_{\lambda}$  are objects on the "*p*-adic side". The next result leads us to  $F_{\lambda}$ .

LEMMA 2.7.2. There exists a lift  $u_{\lambda} \in N$  of  $y_{\lambda}$  such that  $u_{\lambda} \in Z^{1}(\mathbf{F}, N)$ .

*Proof.* If j is the order of  $\sigma_{\lambda}$  (see Lemma 2.7.1), then

$$1 = (w_{\lambda} y_{\lambda} \vartheta)^{j} = w_{\lambda}' (y_{\lambda} \vartheta)^{j},$$

for some  $w'_{\lambda} \in W^{\circ}$ . Since  $W^{\circ}$  acts simply-transitively on alcoves in  $\mathcal{A}$ , we can decompose

$$W \rtimes \langle \vartheta \rangle = W^{\circ} \rtimes \tilde{\Omega}_{C_{\lambda}}$$

where  $\Omega_{C_{\lambda}}$  is the stabilizer of  $C_{\lambda}$  in  $W \rtimes \langle \vartheta \rangle$ . It follows that  $(y_{\lambda}\vartheta)^j = 1$ . Let k be the order of  $\vartheta$ . Then

$$1 = (y_{\lambda}\vartheta)^{jk} = [y_{\lambda}\vartheta(y_{\lambda})\cdots\vartheta^{jk-1}(y_{\lambda})]\vartheta^{jk} = y_{\lambda}\vartheta(y_{\lambda})\cdots\vartheta^{jk-1}(y_{\lambda}).$$

That is,  $y_{\lambda} \in Z^1(\mathbf{F}, W)$ . Hence, for all  $x \in W$ , we have  $x^{-1}y_{\lambda}\vartheta(x) \in Z^1(\mathbf{F}, W)$ .

Recall that  $y_{\lambda}\vartheta \cdot C_{\lambda} = C_{\lambda}$ . Let  $x \in W^{\circ}$  be the element such that  $C_{\lambda} = x \cdot C$ . Then  $y_{\lambda}\vartheta \cdot x \cdot C = x \cdot C$ , so that  $x^{-1}y_{\lambda}\vartheta(x) \in \Omega_C$  (recall C is  $\vartheta$ -stable). By the previous paragraph, we have in fact  $x^{-1}y_{\lambda}\vartheta(x) \in Z^1(\mathcal{F}, \Omega_C)$ .

By Lemma 2.3.4 there is a lift  $n \in Z^1(\mathbf{F}, N)$  of  $x^{-1}y_\lambda \vartheta(x)$  such that  $n \cdot C = C$ . Choose a lift  $\dot{x} \in N$  of x. Then the element

$$u_{\lambda} := \dot{x}n \operatorname{F}(\dot{x})^{-1} \in Z^{1}(\operatorname{F}, N)$$

is a lift of  $y_{\lambda}$  as claimed.

LEMMA 2.7.3. The class of  $u_{\lambda}$  in  $H^1(\mathbf{F}, G)$  is equal to that of  $\dot{\omega}_{\lambda} \in Z^1(\mathbf{F}, G)$ . (See 2.4.3.)

*Proof.* By the construction of  $u_{\lambda}$  in Lemma 2.7.2, we have  $[u_{\lambda}] = [n]$ , where  $n \in Z^1(\mathbf{F}, N)$  is a lift of  $x^{-1}y_{\lambda}\vartheta(x) \in \Omega_C$ , and x is a certain element of  $W^{\circ}$ . By Corollary 2.4.3, it suffices to show that

$$x^{-1}y_{\lambda}\vartheta(x) \in t_{\lambda}W^{\circ}.$$

First note that  $t_{\lambda}W^{\circ}$  is preserved under conjugation by  $W^{\circ}$ . The equation  $t_{\lambda}w = w_{\lambda}y_{\lambda}$  then implies  $y_{\lambda} \in t_{\lambda}W^{\circ}$ . Since  $x \in W^{\circ}$  as well, it follows that  $x^{-1}y_{\lambda}\vartheta(x) \in t_{\lambda}W^{\circ}$ .

Fix once and for all a lift  $\dot{w}$  of w in  $\dot{W}_o$ . Since  $t_{\lambda}wy_{\lambda}^{-1} = w_{\lambda} \in W^{\circ}$ , there exists a unique lift  $\dot{w}_{\lambda} \in N$  of  $w_{\lambda}$  satisfying

$$t_{\lambda}\dot{w} = \dot{w}_{\lambda}u_{\lambda}.$$

Set

$$G_{\lambda} := G_{J_{\lambda}}, \qquad F_{\lambda} := \operatorname{Ad}(u_{\lambda}) \circ F.$$

Since  $y_{\lambda}\vartheta \cdot C_{\lambda} = C_{\lambda}$ , we have

$$F_{\lambda} \cdot C_{\lambda} = C_{\lambda}.$$

Now,

$$t_{\lambda} \in Z^1(\mathbf{F}_w, G), \qquad \dot{w} \in Z^1(\mathbf{F}, G),$$

the first by the definition of  $X_w$  and the second by Lemma 2.1.2 applied to the group  $\dot{W}_o$ . From Lemma 2.1.1 we conclude that

$$t_{\lambda} \dot{w} \in Z^1(\mathbf{F}, G).$$

But also  $u_{\lambda} \in Z^1(\mathbf{F}, G)$ , so that, using Lemma 2.1.1 again, we conclude

$$\dot{w}_{\lambda} \in Z^1(\mathbf{F}_{\lambda}, G_{\lambda}).$$

By Lemma 2.3.1 there is an element  $p_{\lambda} \in G_{\lambda}$  such that

$$p_{\lambda}^{-1} \operatorname{F}_{\lambda}(p_{\lambda}) = \dot{w}_{\lambda}$$

This equation can be written as

(8) 
$$t_{\lambda}\dot{w} = p_{\lambda}^{-1}u_{\lambda} F(p_{\lambda}).$$

It follows that  $t_{\lambda} \dot{w} \in Z^1(\mathbf{F}, G)$ , and, in view of Lemma 2.7.3, we have

(9) 
$$[t_{\lambda}\dot{w}] = [u_{\lambda}] = [\dot{\omega}_{\lambda}] \in H^{1}(\mathbf{F}, G),$$

as claimed in the proof of Lemma 2.6.1.

2.8. A normal form for Frobenius endomorphisms. Keep the set-up of Section 2.7. For each  $\lambda \in X_w$  we have defined a Frobenius automorphism  $F_{\lambda}$  and an  $F_{\lambda}$ -stable alcove  $C_{\lambda}$  in  $\mathcal{A}$ . For certain  $w \in W_o$ , we will eventually associate to  $\lambda$ , and some additional data, a representation  $\pi_{\lambda} \in \operatorname{Irr}(G^{F_{\lambda}})$ . This association will be quite natural, but it will leave us with infinitely many pairs  $(G^{F_{\lambda}}, \pi_{\lambda})$ , which are almost all conjugate to one another in some sense, and we will need to compare them. To do this, we seek a normal form for our Frobenius endomorphisms  $F_{\lambda}$ .

Fix a class  $\omega \in H^1(\mathbf{F}, G)$ , along with a representative  $u \in \omega \cap N$ , such that  $u \cdot C = C$ . This is possible by Lemma 2.3.4. In this section we will gather together all of the  $\mathbf{F}_{\lambda}$  for which  $u_{\lambda} \in \omega$ . We will then use our explicit cohomology picture to keep track of conjugacy classes of tori and certain semisimple elements in a fixed group  $G^{\mathbf{F}_u}$ . This, in turn, will be used in our stability calculations.

From Lemma 2.6.1, we have a map

$$r: X_w \to H^1(\mathbf{F}, G)$$

sending  $\lambda \mapsto [\dot{\omega}_{\lambda}]$ . For  $\lambda \in r^{-1}(\omega)$ , define  $\sigma_{\lambda} = t_{\lambda}w\vartheta$ , and choose  $J_{\lambda}, C_{\lambda}, u_{\lambda}$ as in Section 2.7. Recall that the Frobenius  $F_{\lambda} = \operatorname{Ad}(u_{\lambda}) \circ F$  stabilizes the alcove  $C_{\lambda}$ .

LEMMA 2.8.1. For each  $\lambda \in r^{-1}(\omega)$ , there exists  $m_{\lambda} \in N$  such that

$$m_{\lambda} * u_{\lambda} = u, \qquad m_{\lambda} \cdot C_{\lambda} = C.$$

Proof. Choose  $k_{\lambda} \in N$  such that  $k_{\lambda} \cdot C_{\lambda} = C$ . Since  $F_{\lambda} \cdot C_{\lambda} = C_{\lambda}$ , it follows that  $k_{\lambda} * u_{\lambda} \in N_{C}$ . In Lemma 2.7.3 we proved that  $[u] = [u_{\lambda}]$  in  $H^{1}(F,G)$ . Therefore  $[u] = [k_{\lambda} * u_{\lambda}]$  in  $H^{1}(F,G)$ . Since u and  $k_{\lambda} * u_{\lambda}$  belong to  $N_{C}$ , and  $H^{1}(F,N_{C}) \to H^{1}(F,G)$  is injective (see Lemma 2.3.4), we have  $[u] = [k_{\lambda} * u_{\lambda}]$  in  $H^{1}(F,N_{C})$ . Hence there is  $\ell_{\lambda} \in N_{C}$  such that  $u = (\ell_{\lambda}k_{\lambda}) * u_{\lambda}$ . Then  $m_{\lambda} := \ell_{\lambda}k_{\lambda}$  has the required properties.

As in Section 2.7, we have the alternative expression  $\sigma_{\lambda} = w_{\lambda}y_{\lambda}\vartheta$ , where  $w_{\lambda} \in W_{\lambda}$  and  $y_{\lambda}$  is the image of  $u_{\lambda}$  in W. Recall that we have fixed a lift  $\dot{w} \in \dot{W}_{o}$  of w, which determines a lift  $\dot{w}_{\lambda} \in N \cap G_{\lambda}$  by the equation  $t_{\lambda}\dot{w} = \dot{w}_{\lambda}u_{\lambda}$ , and

we have an element  $p_{\lambda} \in G_{\lambda}$  such that  $p_{\lambda}^{-1} F_{\lambda}(p_{\lambda}) = \dot{w}_{\lambda}$ . Choose  $m_{\lambda}$  as in Lemma 2.8.1 and set

$$q_{\lambda} := m_{\lambda} p_{\lambda} \in G, \quad S_{\lambda} := \operatorname{Ad}(q_{\lambda})T.$$

Then in G we have, using equation (8),

$$q_{\lambda}^{-1} \operatorname{F}_{u}(q_{\lambda}) = p_{\lambda}^{-1} \cdot m_{\lambda}^{-1} u \operatorname{F}(m_{\lambda} \cdot p_{\lambda}) u^{-1} = p_{\lambda}^{-1} u_{\lambda} \operatorname{F}(p_{\lambda}) u^{-1} = t_{\lambda} \dot{w} u^{-1}.$$

Thus, we have the analogue of equation (8) for  $q_{\lambda}$ :

(10) 
$$t_{\lambda}\dot{w} = q_{\lambda}^{-1}u\,\mathbf{F}(q_{\lambda}).$$

Equation (10) will be used repeatedly in future calculations. It implies that the map  $\operatorname{Ad}(q_{\lambda}): T \longrightarrow S_{\lambda}$  satisfies

$$F_u \circ Ad(q_\lambda) = Ad(q_\lambda) \circ F_w$$
.

In particular,  $S_{\lambda}$  is an  $F_u$ -stable unramified maximal torus in G, whose underlying algebraic group  $\mathbf{S}_{\lambda}$  is k-isomorphic to the twist of  $\mathbf{T}$  by w.

In this section we have constructed an infinite family  $\{S_{\lambda} : \lambda \in r^{-1}(\omega)\}$ of such tori, and our next task is to group these tori, and their strongly regular elements, into  $G^{F_u}$ -conjugacy classes.

2.9. *Conjugacy.* We will use several times another consequence of Steinberg's vanishing result, Theorem 2.2.1.

LEMMA 2.9.1. Let  $\mathbf{G}_{ad}$  be the adjoint group of  $\mathbf{G}$ , and let  $G_{ad} = \mathbf{G}_{ad}(K)$ . Suppose  $\mathbf{G}_{ad}$  acts on a k-variety  $\mathbf{X}$ , with connected stabilizers. For  $x, y \in \mathbf{X}(K)$ , the following are equivalent:

- (1) x and y are in the same G-orbit,
- (2) x and y are in the same  $G_{ad}$ -orbit,
- (3) x and y are in the same **G**-orbit.

Here **G** acts on **X** via the canonical map  $j : \mathbf{G} \longrightarrow \mathbf{G}_{ad}$ .

Proof. Implication  $(1) \Rightarrow (2)$  is clear. Since  $\mathbf{G} \longrightarrow \mathbf{G}_{ad}$  is surjective, (2)  $\Rightarrow$  (3) is also clear. Assume (3) holds, so there is  $g \in \mathbf{G}$  such that  $g \cdot x = y$ . Since  $x, y \in \mathbf{X}(K) = \mathbf{X}^{\mathcal{I}}$ , the map sending  $\sigma \in \mathcal{I}$  to  $g^{-1}\sigma(g) \in \mathbf{G}$  is a cocycle in  $Z^{1}(K, \mathbf{G}_{x})$ . By hypothesis,  $\mathbf{G}_{x}$  is the full stabilizer of x in  $\mathbf{G}$ . By Theorem 2.2.1 we have  $H^{1}(K, \mathbf{G}_{x}) = 1$ , so there is  $h \in \mathbf{G}_{x}$  such that  $(gh)^{-1}\sigma(gh) = 1$  for all  $\sigma \in \mathcal{I}$ . Hence  $gh \in G$ , and (1) follows.  $\Box$  We say that  $\gamma \in G^F$  is strongly regular semisimple in G if the centralizer of  $\gamma$  in **G** is a torus. By 2.9.1 we have for such  $\gamma$  the equalities

$$[\mathrm{Ad}(\mathbf{G})\gamma]^{\mathrm{Gal}(\bar{k}/k)} = [\mathrm{Ad}(G_{\mathrm{ad}})\gamma]^F = [\mathrm{Ad}(G)\gamma]^F.$$

Such a set is called the *G*-stable conjugacy-class of  $\gamma$ . It is a finite union of  $\operatorname{Ad}(G^F)$ -orbits, which are called the *rational classes* in the stable class.

2.10. Rational classes in a stable class. We continue with the setup of Section 2.8. Our aim is to explicitly parametrize the rational classes in the stable classes of certain elements  $\gamma \in G$ .

Recall that the map  $r: X_w \longrightarrow H^1(\mathbf{F}, G)$  is defined as a composition

$$r: X_w \longrightarrow [X/(1-w\vartheta)X]_{tor} \longrightarrow H^1(\mathbf{F}, G).$$

We have fixed  $\omega \in H^1(\mathbf{F}, G)$ , and have considered the fiber  $r^{-1}(\omega) \subset X_w$ . Now let  $[r^{-1}(\omega)]$  denote the image of  $r^{-1}(\omega)$  in  $[X/(1-w\vartheta)X]_{\text{tor}}$ . In other words,  $[r^{-1}(\omega)]$  is the fiber over  $\omega$  in the second map in the above composition. By Lemma 2.6.1, we may identify  $[r^{-1}(\omega)]$  with the fiber over  $\omega$  of the natural map  $H^1(\mathbf{F}_w, T) \longrightarrow H^1(\mathbf{F}, G)$ .

Let  $\gamma \in T^{F_w}$  be a strongly regular element of G. For  $\lambda \in r^{-1}(\omega)$ , we set

$$\gamma_{\lambda} := q_{\lambda} \gamma q_{\lambda}^{-1} \in S_{\lambda}^{\mathbf{F}_u}.$$

LEMMA 2.10.1. For  $\lambda, \mu \in r^{-1}(\omega)$ , the elements  $\gamma_{\lambda}$  and  $\gamma_{\mu}$  are  $G^{F_u}$ -conjugate if and only if  $\lambda \equiv \mu \mod (1 - w\vartheta)X$ . Thus, sending  $\lambda \mapsto \gamma_{\lambda}$  defines a bijection

$$[r^{-1}(\omega)] \xrightarrow{\sim} [\operatorname{Ad}(G)\gamma]^{\operatorname{F}_u}/G^{\operatorname{F}_u}.$$

*Proof.* Since  $S_{\lambda} = G_{\gamma_{\lambda}}$ , this is almost obvious from Lemma 2.6.1. However, we will give a direct proof which produces the conjugation from elements already in play.

By Equation (10) we have

$$q_{\lambda}^{-1} u \operatorname{F}(q_{\lambda}) = t_{\lambda} \dot{w}, \qquad q_{\mu}^{-1} u \operatorname{F}(q_{\mu}) = t_{\mu} \dot{w}.$$

Let  $h = q_{\mu}q_{\lambda}^{-1}$ , so that  $\operatorname{Ad}(h)\gamma_{\lambda} = \gamma_{\mu}$ . Then  $h^{-1}\operatorname{F}_{u}(h) \in S_{\lambda}$  since  $\gamma$  is strongly regular. Moreover,  $\gamma_{\mu} \in \operatorname{Ad}(G^{\operatorname{F}_{u}})\gamma_{\lambda}$  if and only if the class  $[h^{-1}\operatorname{F}_{u}(h)]$  in  $H^{1}(\operatorname{F}_{u}, S_{\lambda})$  is the identity element. We have

$$h^{-1} \operatorname{F}_{u}(h) = q_{\lambda} \cdot q_{\mu}^{-1} u \operatorname{F}(q_{\mu}) \cdot \operatorname{F}(q_{\lambda})^{-1} u^{-1}$$
$$= q_{\lambda} t_{\mu} \dot{w} \operatorname{F}(q_{\lambda})^{-1} u^{-1}$$
$$= q_{\lambda} t_{\mu} \dot{w} \dot{w}^{-1} t_{-\lambda} q_{\lambda}^{-1}$$
$$= q_{\lambda} t_{\mu-\lambda} q_{\lambda}^{-1},$$

so that

$$[h^{-1} \operatorname{F}_{u}(h)] = [q_{\lambda} t_{\mu-\lambda} q_{\lambda}^{-1}] \in H^{1}(\operatorname{F}_{u}, S_{\lambda}).$$

On the other hand, we have isomorphisms

$$[X/(1-w\vartheta)X]_{\mathrm{tor}} \xrightarrow{\sim} H^1(\mathbf{F}_w,T) \xrightarrow{\mathrm{Ad}(q_\lambda)} H^1(\mathbf{F}_u,S_\lambda).$$

The first isomorphism is Corollary 2.4.3 applied to  $T, F_w$ ; for  $\nu \in X_w$ , it sends the class of  $\nu \mod (1-w\vartheta)X$  to the class of  $t_{\nu}$  in  $H^1(F_w, T)$ . Thus,  $[q_{\lambda}t_{\mu-\lambda}q_{\lambda}^{-1}]$ is trivial in  $H^1(F_u, S_{\lambda})$  if and only if  $\lambda - \mu \in (1-w\vartheta)X$ .

2.11. A partition of the rational classes in a stable class. We have seen in Lemma 2.10.1 that the fiber  $[r^{-1}(\omega)]$  parametrizes the  $G^{F_u}$ -conjugacy classes in the stable class of  $\gamma_{\lambda}$ , for  $\lambda \in r^{-1}(\omega)$ . In this section we study an additional structure on this fiber. Namely, the group

$$W_o^{w\vartheta} := \{z_o \in W_o : w\vartheta(z_o)w^{-1} = z_o\}$$

acts naturally on  $X_w$ ,  $[X/(1-w\vartheta)X]_{tor}$ , and  $[\bar{X}/(1-\vartheta)\bar{X}]_{tor}$ , and  $W_o^{w\vartheta}$  acts trivially on the latter. Hence there is a natural  $W_o^{w\vartheta}$ -action on the fiber  $[r^{-1}(\omega)]$ . This action in fact corresponds to  $G^{F_u}$ -conjugacy among the family of tori  $\{S_{\lambda} : \lambda \in r^{-1}(\omega)\}$ , as follows.

LEMMA 2.11.1. For  $\lambda, \mu \in r^{-1}(\omega)$  the following are equivalent.

- (1) There is  $z_o \in W_o^{w\vartheta}$  such that  $z_o \mu \equiv \lambda \mod (1 w\vartheta)X$ .
- (2) There is  $g \in G^{\mathbf{F}_u}$  such that  ${}^g \gamma_{\mu} \in S_{\lambda}$ .
- (3) There is  $g \in G^{\mathbf{F}_u}$  such that  ${}^gS_{\mu} = S_{\lambda}$ .

*Proof.* Assertions (2) and (3) are equivalent because  $S_{\lambda} = G_{\gamma_{\lambda}}$  for all  $\lambda \in r^{-1}(\omega)$ . (We have made them separate statements for later convenience.)

Assume (3) holds. Then  $q_{\lambda}^{-1}gq_{\mu} \in N$ . Applying Equation (10) for  $\mu$  and  $\lambda$ , we find that

(11)  

$$q_{\lambda}^{-1}gq_{\mu} \cdot t_{\mu}\dot{w} \cdot \mathcal{F}(q_{\mu}^{-1}g^{-1}q_{\lambda}) = q_{\lambda}^{-1}gu\,\mathcal{F}(g)^{-1}\,\mathcal{F}(q_{\lambda})$$

$$= q_{\lambda}^{-1}g \cdot u\,\mathcal{F}(g)^{-1}u^{-1} \cdot q_{\lambda}t_{\lambda}\dot{w}$$

$$= q_{\lambda}^{-1}g \cdot \mathcal{F}_{u}(g)^{-1} \cdot q_{\lambda}t_{\lambda}\dot{w}$$

$$= t_{\lambda}\dot{w}.$$

Let  $z \in W$  be the image of  $q_{\lambda}^{-1}gq_{\mu}$ , and write  $z = t_{\nu}z_{o}$  with  $\nu \in X$ ,  $z_{o} \in W_{o}$ . Mapping the first and last terms of Equation (11) to W, we have

$$t_{\nu}z_{o} \cdot t_{\mu}w \cdot \vartheta(z_{o}^{-1}t_{-\nu}) = t_{\lambda}w.$$

This shows that  $z_o \in W_o^{w\vartheta}$ , and then projection onto  $W_o$  yields

$$\lambda = z_o \mu + (1 - w\vartheta)\nu,$$

so (1) holds.

819

Conversely, if (1) holds, then  $\lambda = z_o \mu + (1 - w \vartheta) \nu$  for some  $\nu \in X$ , and we set  $z = t_\nu z_o$ . Since  $H^1(\mathbf{F}_w, {}^0T) = 1$ , there is a lift  $\dot{z}_o \in N^{\mathbf{F}_w}$  of  $z_o$ , and we set  $\dot{z} = t_\nu \dot{z}_o$ . Then

$$\mathbf{F}(\dot{z}) = t_{\vartheta\nu} \dot{w}^{-1} \dot{z}_o \dot{w}.$$

Set  $g = q_{\lambda} \dot{z} q_{\mu}^{-1}$ . It is clear that  ${}^{g}S_{\mu} = S_{\lambda}$ . To prove (3), it remains to show that  $g \in G^{F_{u}}$ . Using equation (10) again, we compute

$$\begin{aligned} \mathbf{F}_{u}(g) &= u \, \mathbf{F}(q_{\lambda}) \cdot \mathbf{F}(\dot{z}) \cdot \mathbf{F}(q_{\mu})^{-1} u^{-1} \\ &= q_{\lambda} t_{\lambda} \dot{w} \cdot t_{\vartheta\nu} \dot{w}^{-1} \dot{z}_{o} \dot{w} \cdot \dot{w}^{-1} t_{-\mu} q_{\mu}^{-1} \\ &= q_{\lambda} \cdot t_{\lambda + w \vartheta \nu - z_{o} \mu} \cdot \dot{z}_{o} q_{\mu}^{-1} \\ &= q_{\lambda} t_{\nu} \dot{z}_{o} q_{\mu}^{-1} \\ &= g, \end{aligned}$$

as desired.

Let

$$W^{w\vartheta}_{o,\lambda} := \{z \in W^{w\vartheta}_o: \ z\lambda \equiv \lambda \mod (1-w\vartheta)X\}$$

be the stabilizer in  $W_o^{w\vartheta}$  of the class of  $\lambda$  in  $[r^{-1}(\omega)]$ . The next result interprets  $W_o^{w\vartheta}$  and  $W_{o,\lambda}^{w\vartheta}$  as "large" and "small" Weyl groups of  $S_{\lambda}$ , respectively. This will be used to relate *L*-packets to stable conjugacy classes of tori.

LEMMA 2.11.2. For 
$$\lambda \in r^{-1}(\omega)$$
, the map  $\operatorname{Ad}(q_{\lambda})$  induces isomorphisms  
 $W_{o}^{w\vartheta} \xrightarrow{\sim} N(G, S_{\lambda}^{F_{u}})/S_{\lambda}, \qquad W_{o,\lambda}^{w\vartheta} \xrightarrow{\sim} N(G, S_{\lambda})^{F_{u}}/S_{\lambda}^{F_{u}}.$ 

*Proof.* First, a remark about normalizers of tori. Let F be a Frobenius on G arising from some k-structure, and let S be the group of K-points of a maximal k-torus  $\mathbf{S} \subset \mathbf{G}$ . We claim that

(12) 
$$\left[N(G,S)/S\right]^F = N(G,S^F)/S.$$

For  $\subseteq$ : Let  $n \in N(G, S)$  be such that F(n) = ns for some  $s \in S$ . Then on S we have  $\operatorname{Ad}(n) \circ F = F \circ \operatorname{Ad}(n)$ , implying that  $n \in N(G, S^F)$ . For  $\supseteq$ : Choose  $s_0 \in S^F \cap G^{\operatorname{srss}}$ . For  $n \in N(G, S^F)$ , and  $s \in S$ , the element  $nsn^{-1}$  centralizes  $s_0$ , hence lies in S. This shows that  $N(G, S^F) \subseteq N(G, S)$ . Moreover, we have  $\operatorname{Ad}(n)s_0 \in S^F$ , implying that  $\operatorname{Ad}(n^{-1}F(n))s_0 = s_0$ ; hence  $F(n) \in nS$ , as desired.

This remark shows that  $W_o^{w\vartheta} = N(G, T^{F_w})/T$ , and the first isomorphism follows. The second isomorphism amounts to showing that the projections  $N \to W \to W_o$  induce an isomorphism

(13) 
$$N^{\mathbf{F}_{t_{\lambda}w}}/T^{\mathbf{F}_{w}} \longrightarrow W^{w\vartheta}_{o,\lambda}.$$

Let  $n \in N^{\mathcal{F}_{t_{\lambda}w}}$ , and let  $t_{\nu}z$  be the image of n in W, where  $\nu \in X$  and  $z \in W_o$ . We want to show that  $z \in W_{o,\lambda}^{w\vartheta}$ . From the equation  $\operatorname{Ad}(t_{\lambda}) \mathcal{F}_w(n) = n$ , we get

$$\operatorname{Ad}(t_{\lambda}w)\vartheta(t_{\nu}z) = t_{\nu}z,$$

which leads to

$$t_{\lambda+(w\vartheta-1)\nu} \operatorname{Ad}(w)\vartheta(z) = t_{z\lambda}z;$$

hence  $z \in W_o^{w\vartheta}$  and  $z\lambda = \lambda + (w\vartheta - 1)\nu$ , as desired. This shows also that (13) is injective.

To see that (13) is surjective, let  $z \in W_{o,\lambda}^{w\vartheta}$ , and choose a lift  $\dot{z} \in N_o$ . Since  $\operatorname{Ad}(t_{\lambda}w)\vartheta(z) = z$  in  $W_o = N_o/{}^0T$ , we have

$$\operatorname{Ad}(t_{\lambda}) \operatorname{F}_{w}(\dot{z}) = \dot{z}t,$$

for some  $t \in {}^{0}T$ . Since  $H^{1}(\mathbf{F}_{w}, {}^{0}T) = 1$  we can write  $t = s \mathbf{F}_{w}(s^{-1})$  for some  $s \in {}^{0}T$ . Then  $\dot{z}s$  is a lift of z in  $N^{\mathbf{F}_{t_{\lambda}w}}$ .

### 3. The conjectural local Langlands correspondence

Very roughly speaking, the conjectural local Langlands correspondence predicts a relationship between representations of a p-adic group and certain maps from the Weil group into the dual group. The latter maps are called "Langlands parameters"; they should partition the representations of the p-adic group into finite sets, called "L-packets", and it is conjectured that these L-packets have many nice properties. We now make these statements more precise.

3.1. Frobenius endomorphisms and representations of p-adic groups. Continue with the set-up of Section 2.3: **G** is a connected reductive k-group which is k-quasi-split and K-split, with Frobenius automorphism F on the group  $G = \mathbf{G}(K)$ .

For each cocycle  $u \in Z^1(\mathbf{F}, G)$ , we have a twisted Frobenius

$$\mathbf{F}_u := \mathrm{Ad}(u) \circ \mathbf{F}$$

on G, and for  $g \in G$ , we have

$$\operatorname{Ad}(g) \circ \operatorname{F}_{u} \circ \operatorname{Ad}(g)^{-1} = \operatorname{F}_{q * u}.$$

Therefore Ad(g) is an isomorphism

$$\mathrm{Ad}(g): G^{\mathrm{F}_u} \longrightarrow G^{\mathrm{F}_{g*u}},$$

which induces a bijection on irreducible representations, denoted by

$$\operatorname{Ad}(g)_* : \operatorname{Irr}(G^{\mathcal{F}_u}) \longrightarrow \operatorname{Irr}(G^{\mathcal{F}_{g*u}})$$

This bijection preserves the sets  $Irr^2(\cdot)$  of square-integrable representations.

Thus we have a G-action on the set

$$\mathcal{R}^{2}(\mathbf{F},G) := \{(u,\pi): \ u \in Z^{1}(\mathbf{F},G), \ \pi \in \mathrm{Irr}^{2}(G^{\mathbf{F}_{u}})\}.$$

820

Considering the *u*-coordinate, we can partition  $\mathcal{R}^2(\mathbf{F}, G)$  into *G*-stable subsets

$$\mathcal{R}^2(\mathbf{F},G) = \coprod_{\omega \in H^1(\mathbf{F},G)} \mathcal{R}^2(\mathbf{F},G,\omega),$$

where  $\mathcal{R}^2(\mathbf{F}, G, \omega)$  consists of the pairs  $(u, \pi) \in \mathcal{R}^2(\mathbf{F}, G)$  with  $u \in \omega$ .

3.2. Dual group. Let  $\hat{G}$  be the dual group of **G**. By definition, the dual torus

$$\hat{T} := Y \otimes \mathbb{C}^{\times}$$

is a maximal torus in  $\hat{G}$ . The operator  $\hat{\vartheta} \in \operatorname{Aut}(Y)$  dual to  $\vartheta$  extends to an automorphism of the torus  $\hat{T}$ , with trivial action on  $\mathbb{C}^{\times}$ .

We choose, once and for all, a pinning  $(\hat{T}, \hat{B}, \{x_{\alpha}\})$  where  $\hat{B}$  is a Borel subgroup of  $\hat{G}$  containing  $\hat{T}$  and the  $x_{\alpha}$  are nontrivial elements in the simple root groups of  $\hat{T}$  in  $\hat{B}$ . There is a unique extension of  $\hat{\vartheta}$  to an automorphism of  $\hat{G}$ , satisfying  $\hat{\vartheta}(x_{\alpha}) = x_{\vartheta \cdot \alpha}$  (see [7]). We can then form the semidirect product

$${}^{L}G := \langle \hat{\vartheta} \rangle \ltimes \hat{G}.$$

3.3. Weil group. Recall that the inertia subgroup  $\mathcal{I} \leq \operatorname{Gal}(\bar{k}/k)$  is the kernel of the natural map

$$\operatorname{Gal}(\overline{k}/k) \longrightarrow \operatorname{Gal}(K/k).$$

The Weil group  $\mathcal{W}$  is the subgroup of  $\operatorname{Gal}(\overline{k}/k)$  generated by  $\mathcal{I}$  and the Frobenius Frob. The wild inertia subgroup  $\mathcal{I}^+ \triangleleft \mathcal{I}$  is the maximal pro-*p* subgroup of  $\mathcal{I}$ . The tame inertia group is the quotient  $\mathcal{I}_t := \mathcal{I}/\mathcal{I}^+$ , and the tame Weil group is the quotient  $\mathcal{W}_t := \mathcal{W}/\mathcal{I}^+$ . We will have more to say about these groups in Section 4.3.

3.4. Elliptic Langlands parameters. An elliptic Langlands parameter is a homomorphism

$$\varphi: \mathcal{W} \times \mathrm{SL}_2(\mathbb{C}) \longrightarrow {}^L G$$

with the following properties:

- $\varphi(\mathcal{I})$  is a finite subgroup of  $\hat{G}$ ,
- $\varphi(\text{Frob}) = \hat{\vartheta}f$ , where  $f \in \hat{G}$  is semisimple,
- The restriction of  $\varphi$  to  $SL_2(\mathbb{C})$  is algebraic.
- The identity component  $C_{\hat{G}}(\varphi)^{\circ}$  of  $C_{\hat{G}}(\varphi)$  is equal to the identity component  $(\hat{Z}^{\hat{\vartheta}})^{\circ}$  of  $\hat{Z}^{\hat{\vartheta}}$ .

The last condition expresses the "ellipticity" of  $\varphi$ ; it is equivalent to requiring that the image of  $\varphi$  not be contained in a proper Levi subgroup of  ${}^{L}G$ , where the meaning of "Levi subgroup" is as in [7, 3.4].

821

We let  $C_{\varphi}$  denote the component group of  $C_{\hat{G}}(\varphi)$ . Since  $\hat{Z}^{\hat{\vartheta}}$  is contained in the center of  $C_{\hat{G}}(\varphi)$ , each  $\rho \in \operatorname{Irr}(C_{\varphi})$  determines a central character on  $\hat{Z}^{\hat{\vartheta}}$  hence, via Kottwitz' isomorphism (Corollary 2.4.3), a class  $\omega_{\rho} \in H^1(\mathcal{F}, G)$ . Thus we may partition

$$\operatorname{Irr}(C_{\varphi}) = \coprod_{\omega \in H^1(\mathcal{F}, G)} \operatorname{Irr}(C_{\varphi}, \omega),$$

where  $\operatorname{Irr}(C_{\varphi}, \omega)$  consists of the representations  $\rho \in \operatorname{Irr}(C_{\varphi})$  with  $\omega_{\rho} = \omega$ .

3.5. The conjectures. The version of the Langlands conjectures stated here is the product of many refinements, by Deligne, Lusztig, Vogan and others. The local Langlands correspondence for **G** is a conjectural bijection between the set of  $\hat{G}$ -orbits of pairs  $(\varphi, \rho)$ , where  $\varphi$  is an elliptic Langlands parameter and  $\rho \in \operatorname{Irr}(C_{\varphi})$ , and the set of *G*-orbits in  $\mathcal{R}^2(\mathbf{F}, G)$ . Among many other expected properties, the *G*-orbit corresponding to  $(\varphi, \rho)$  should lie in  $\mathcal{R}^2(\mathbf{F}, G, \omega)$ precisely when  $\omega_{\rho} = \omega$ .

Thus, we expect to have, for each  $\hat{G}$ -conjugacy class of elliptic Langlands parameters  $\varphi$ , a finite set

$$\Pi(\varphi) = \coprod_{\omega \in H^1(\mathcal{F}, G)} \Pi(\varphi, \omega),$$

where

(14) 
$$\Pi(\varphi,\omega) := \{ [\pi(\varphi,\rho)] : \rho \in \operatorname{Irr}(C_{\varphi},\omega) \},\$$

and  $[\pi(\varphi, \rho)] = \{(u, \pi_u(\varphi, \rho)) : u \in \omega\}$  is a *G*-orbit in  $\mathcal{R}^2(\mathbf{F}, G, \omega)$ .

These putative sets  $\Pi(\varphi)$  are known as "*L*-packets". These *L*-packets should form partitions

$$\mathcal{R}^{2}(\mathbf{F},G)/G = \coprod_{\{\varphi\}/\hat{G}} \Pi(\varphi), \qquad \mathcal{R}^{2}(\mathbf{F},G,\omega)/G = \coprod_{\{\varphi\}/\hat{G}} \Pi(\varphi,\omega).$$

To describe the properties we expect of an *L*-packet, we fix a representative  $u \in Z^1(\mathbf{F}, N)$  of each class  $\omega \in H^1(\mathbf{F}, G)$ . We represent the trivial class by u = 1, recalling that  $\mathbf{F}_1 = \mathbf{F}$ . Then  $\{\pi_u(\varphi, \rho) : \rho \in \operatorname{Irr}(C_{\varphi}, \omega)\}$  is a set of representatives for the *G*-orbits comprising  $\Pi(\varphi, \omega)$ .

We expect *L*-packets to have the following properties.

(i) The representation  $\pi_u(\varphi, \rho)$  is unipotent [39] if and only if  $\varphi$  is unramified, (that is, if  $\varphi$  is trivial on the inertia subgroup  $\mathcal{I}$  of  $\mathcal{W}$ ). For **G** with connected center, Lusztig has constructed unipotent *L*-packets corresponding to unramified  $\varphi$  [39], [40]. See also [41] and [48] and for orthogonal and split adjoint exceptional groups, respectively.

(ii)  $\pi_u(\varphi, \rho)$  has depth-zero (that is, has nonzero vectors fixed under the pro-unipotent radical of some parahoric subgroup in  $G^{\mathbf{F}_u}$ ) if and only if  $\varphi$  is tame (that is,  $\varphi$  is trivial on the wild inertia subgroup  $\mathcal{I}^+$  of  $\mathcal{I}$ ).

(iii)  $\pi_1(\varphi, 1)$  should be generic (that is, have a Whittaker model). If **G** has a connected center, then  $\pi_1(\varphi, 1)$  should be the unique generic representation in  $\Pi(\varphi)$ .

(iv) Let  ${}^{L}M$  be a minimal Levi subgroup of  ${}^{L}G$  containing  $\varphi(\mathcal{W})$ . (It is unique up to conjugacy by the connected centralizer of  $\varphi(\mathcal{W})$  [7].) If  ${}^{L}M = {}^{L}G$ , then every class in  $\Pi(\varphi)$  should consist of supercuspidal representations. In this case, we say that  $\Pi(\varphi)$  itself is "supercuspidal". The *L*-packets in this paper are all supercuspidal.

If  ${}^{L}M \neq {}^{L}G$ , then  ${}^{L}M$  corresponds to an F-stable Levi subgroup  $M \subset G$ contained in an F-stable proper parabolic subgroup  $P \subset G$ . The restriction  $\varphi$ :  $\mathcal{W} \longrightarrow {}^{L}M$  inductively corresponds to a generic supercuspidal representation  $\pi_{1}^{M}(\varphi, 1)$  of  $M^{\mathrm{F}}$ , and  $\pi_{1}(\varphi, 1)$  should be a generic constituent of the smoothly induced representation  $\mathrm{Ind}_{P^{\mathrm{F}}}^{G^{\mathrm{F}}} \pi_{1}^{M}(\varphi, 1)$ . For  $(u, \rho) \neq (1, 1)$ , the representation  $\pi_{u}(\varphi, \rho)$  should be supported on Levi subgroups of  $G^{\mathrm{F}_{u}}$  whose center has k-rank no larger than that of  $M^{\mathrm{F}}$ .

(v) For each u, normalize Haar measure on  $G^{F_u}$  so that the formal degree of the Steinberg representation of  $G^{F_u}$  is independent of u. (For example, one could make all Steinberg formal degrees equal to one, but we will choose a different normalization.) Let Deg denote formal degree with respect to these measures. Then we should have

$$\operatorname{Deg}[\pi_u(\varphi, \rho)] = \dim \rho \cdot \operatorname{Deg}[\pi_1(\varphi, 1)].$$

Recall that  $\pi_u(\varphi, \rho)$  and  $\pi_1(\varphi, 1)$  may be representations of nonisomorphic groups.

Properties (i-v) were verified in [48] for unipotent L-packets of split adjoint exceptional groups (see (i) above).

(vi) Fix u and  $\varphi$ , and let  $\Theta_{\rho}$  be the character of  $\pi_u(\varphi, \rho)$ , viewed as a function on the set  $(G^{rss})^{F_u}$  of regular semisimple elements of  $G^{F_u}$ . The function

$$\sum_{\in \operatorname{Irr}(C_{\varphi},\omega)} \dim \rho \cdot \Theta_{\rho}$$

 $\rho$ 

should be stable. That is, if  $\gamma, \gamma' \in (G^{\text{srss}})^{F_u}$  are *G*-conjugate<sup>1</sup>, strongly regular elements (see §1), then we should have

$$\sum_{\rho \in \operatorname{Irr}(C_{\varphi},\omega)} \dim \rho \cdot \Theta_{\rho}(\gamma) = \sum_{\rho \in \operatorname{Irr}(C_{\varphi},\omega)} \dim \rho \cdot \Theta_{\rho}(\gamma').$$

This was verified in [41] for unipotent L-packets for inner forms of SO(2n+1) (see (i) above).

<sup>&</sup>lt;sup>1</sup>It is customary to require the elements to be **G**-conjugate, but we have seen in Lemma 2.9.1 that two strongly regular, semisimple elements of G are **G**-conjugate if and only if they are G-conjugate.

# 4. From tame regular semisimple parameters to depth-zero supercuspidal *L*-packets

We shall construct L-packets satisfying (ii)-(vi) above, for tame parameters  $\varphi$  in "general position". We will first make this condition precise, and outline the construction.

Our construction relies on the tame Langlands correspondence for tori. A general Langlands correspondence for tori was proved by Langlands [37] but it seems more difficult to extract the depth-zero correspondence from [37] than to re-prove it from scratch, so we give a short self-contained account of the tame Langlands correspondence for tori. Then we construct our L-packets, using the material from Section 2.7.

4.1. Tame regular semisimple parameters. We say that a Langlands parameter  $\varphi$  is tame regular semisimple if it is trivial on the wild inertia subgroup  $\mathcal{I}^+$  and the centralizer of  $\varphi(\mathcal{I})$  in  $\hat{G}$  is a torus. The latter condition is what we mean by "general position". This forces  $\varphi$  to be trivial on  $SL_2(\mathbb{C})$ . (There is a more general notion of "tame regular" parameter which we will consider elsewhere.)

Recall that  $\mathcal{W}_t = \mathcal{W}/\mathcal{I}^+$  and  $\mathcal{I}_t = \mathcal{I}/\mathcal{I}^+$ . Our choice of inverse Frobenius determines a splitting

$$\mathcal{W}_t = \langle \operatorname{Frob} \rangle \ltimes \mathcal{I}_t,$$

where  $\operatorname{Frob}^{-1} x \operatorname{Frob} = x^q$  for  $x \in \mathcal{I}_t$ .

Recall that the Weyl group N/T is identified with  $W_o$ , the image of  $N_o$  in W. We let  $\hat{W}_o$  denote the Weyl group  $\hat{N}/\hat{T}$  where  $\hat{N}$  is the normalizer of  $\hat{T}$  in  $\hat{G}$ . The restriction of the duality map

$$\operatorname{Aut}(X) \xrightarrow{\sigma \mapsto \hat{\sigma}} \operatorname{Aut}(Y)$$

defines an anti-isomorphism  $w \mapsto \hat{w}$  from  $W_o$  to  $\hat{W}_o$ .

After conjugating by  $\hat{G}$ , we may assume that  $\varphi(\mathcal{I}_t) \subset \hat{T}$  and  $\varphi(\text{Frob}) = \hat{\vartheta}f$ , where  $f \in \hat{N}$ . Let  $\hat{w}$  be the image of f in  $\hat{W}_o$ , corresponding to  $w \in W_o$  via the above anti-isomorphism.

Then

$$C_{\hat{G}}(\varphi) = \hat{T}^{w\vartheta},$$

which implies that the restriction map  $X \to \text{Hom}(\hat{T}^{\widehat{w\vartheta}}, \mathbb{C}^{\times})$  induces an isomorphism

(15) 
$$\left[X/(1-w\vartheta)X\right]_{\text{tor}} \xrightarrow{\sim} \operatorname{Irr}(C_{\varphi}), \quad \lambda \mapsto \rho_{\lambda}$$

Moreover,  $\varphi$  is elliptic if and only if

$$(\hat{T}^{w\vartheta})^{\circ} = (\hat{Z}^{\vartheta})^{\circ}.$$

To summarize: A tame regular semisimple elliptic Langlands parameter (TRSELP) is given by two objects:

- a continuous homomorphism  $s: \mathcal{I}_t \longrightarrow \hat{T}$ , with  $C_{\hat{G}}(s) = \hat{T}$ , and
- an element  $f \in \hat{N}$  satisfying the two conditions

$$\hat{\vartheta} \circ \operatorname{Ad}(f) \circ s^q = s, \qquad (\hat{T}^{w\vartheta})^\circ = (\hat{Z}^\vartheta)^\circ,$$

where  $w \in W_o$  arises from f as above.

Remark 4.1.1. If  $\hat{G}$  is semisimple, then the ellipticity condition on  $\varphi$  is that  $\hat{T}^{\widehat{w\vartheta}}$  be finite. In this case, the map  $\hat{T} \longrightarrow \hat{T}$  given by  $t \mapsto t^{-1}\widehat{w\vartheta}(t)$  has finite fibers, hence is surjective. Thus, if we conjugate  $\hat{\vartheta}f$  by elements of  $\hat{T}$ , we can change f to any other representative of  $\hat{w}$ . This means the  $\hat{T}$ -conjugacy class of  $\hat{\vartheta}f$  is determined by the image  $\hat{w}$  of f in  $\hat{W}_o$ , and so the  $\hat{G}$ -conjugacy classes of TRSELPs are in bijection with  $\hat{W}_o$ -conjugacy classes of pairs  $(s, \hat{w})$ , where  $s: \mathcal{I}_t \longrightarrow \hat{T}$  is continuous, with  $C_{\hat{G}}(s) = \hat{T}$ , and  $\hat{w} \in \hat{W}_o$  satisfies

$$\widehat{w\vartheta} \circ s^q = s, \qquad \widehat{T}^{w\vartheta}$$
 is finite.

4.2. Outline of the construction. Suppose we have a TRSELP  $\varphi$ , with  $s, f, \hat{w}$  as above. Recall from Section 2.7 that  $X_w$  denotes the preimage in X of  $[X/(1 - w\vartheta)X]_{\text{tor}}$ . For  $\lambda \in X_w$ , let  $\rho_{\lambda}$  be as in (15). In Section 2.7 we associated to  $\lambda$  a cocycle  $u_{\lambda}$  whose class in  $H^1(\mathbf{F}, G)$  is  $\omega_{\rho_{\lambda}}$ . The twisted Frobenius  $F_{\lambda} = F_{u_{\lambda}}$  stabilizes a facet  $J_{\lambda} \subset \mathcal{A}$  with corresponding parahoric subgroup  $G_{\lambda}$ . Ellipticity will imply that the facet  $J_{\lambda}$  is in fact a minimal  $F_{\lambda}$ -stable facet in  $\mathcal{A}$ , so that  $G_{\lambda}^{F_{\lambda}}$  is a maximal parahoric subgroup of  $G^{F_{\lambda}}$ .

To  $(\varphi, \lambda)$  we will further associate an  $F_{\lambda}$ -minisotropic torus  $T_{\lambda}$ , a depthzero character  $\chi_{\lambda}$  of  $T_{\lambda}$ , whence an irreducible cuspidal representation  $\kappa_{\lambda}^{0}$  of  $G_{\lambda}^{F_{\lambda}} := (G_{\lambda}/G_{\lambda}^{+})^{F_{\lambda}}$  (viewed as a representation of  $G_{\lambda}^{F_{\lambda}}$ ), via the Deligne-Lusztig construction. In fact,  $\chi_{\lambda}$  will define an extension  $\kappa_{\lambda}$  of  $\kappa_{\lambda}^{0}$  to  $Z^{F}G_{\lambda}^{F_{\lambda}}$  such that the smoothly induced representation

$$\pi_{\lambda} := \operatorname{Ind}_{Z^{\mathrm{F}}G_{\lambda}^{\mathrm{F}_{\lambda}}}^{G^{\mathrm{F}_{\lambda}}} \kappa_{\lambda}$$

is irreducible. Here Z denotes the group of K-rational points of the maximal k-split torus in the center of **G**. An exercise shows that the functions in  $\pi_{\lambda}$  necessarily have compact support modulo  $Z^{\rm F}$ , so we could just as well define  $\pi_{\lambda}$  using the compact induction functor ind.

In our construction,  $u_{\lambda}$  and  $J_{\lambda}$  are not uniquely defined, but the *G*-orbit  $[u_{\lambda}, \pi_{\lambda}] \in \mathcal{R}^2(\mathbf{F}, G)$  will be independent of the choices of  $u_{\lambda}$  and  $J_{\lambda}$ . Moreover, for  $\lambda, \mu \in X_w$ , we will have

$$[u_{\lambda}, \pi_{\lambda}] = [u_{\mu}, \pi_{\mu}] \quad \Leftrightarrow \quad \rho_{\lambda} = \rho_{\mu}.$$

Thus, to  $(\varphi, \rho)$  we will associate the *G*-orbit  $[u_{\lambda}, \pi_{\lambda}] \in \mathcal{R}^2(\mathbf{F}, G, \omega_{\rho})$ , where  $\lambda \in X_w$  is any character of  $\hat{T}$  restricting to  $\rho$ .

The *L*-packets thus defined are the "natural" ones: All choices involved in the construction are rendered equivalent by taking *G*-orbits. However, to make the stability calculations, we need representations of a fixed group. Using Section 2.8, we will choose a representative  $(u, \pi)$  in each *G*-orbit  $[u_{\lambda}, \pi_{\lambda}]$ , so as to have all representations in the "unnatural" *L*-packet living on the single group  $G^{\mathbf{F}_u}$ .

4.3. Depth zero characters of unramified tori. Recall that  $X = X_*(\mathbf{T})$ ,  $Y = X^*(\mathbf{T})$ . Let  $\sigma \in \operatorname{Aut}(X)$  be an automorphism of X of order n, and let  $F_{\sigma} = \sigma \otimes \operatorname{Frob}^{-1}$  be the corresponding twisted Frobenius of both  $T = X \otimes K^{\times}$  and  $\mathsf{T} = X \otimes \mathfrak{F}^{\times}$ . (Recall that  $\operatorname{Frob}^{-1}$  is the q-power map on  $\mathfrak{F}$ .) Let  $\mathfrak{f}_n$  be the degree n extension of  $\mathfrak{f}$  contained in  $\mathfrak{F}$ . Since  $\sigma$  has order n, the torus  $\mathsf{T}$  with Frobenius  $\mathsf{F}_{\sigma}$  splits over  $\mathfrak{f}_n$ , and  $\mathsf{T}^{\mathsf{F}_{\sigma}^n} = X \otimes \mathfrak{f}_n^{\times}$ .

Given automorphisms  $\alpha, \beta$  of abelian groups A, B, respectively, let

$$\operatorname{Hom}_{\alpha,\beta}(A,B)$$

denote the set of homomorphisms  $f: A \longrightarrow B$  such that  $f \circ \alpha = \beta \circ f$ .

We have an exact sequence

$$1 \longrightarrow \mathsf{T}^{\mathrm{F}_{\sigma}} \longrightarrow \mathsf{T}^{\mathrm{F}_{\sigma}^{n}} \stackrel{1-\mathrm{F}_{\sigma}}{\longrightarrow} \mathsf{T}^{\mathrm{F}_{\sigma}^{n}} \stackrel{N_{\sigma}}{\longrightarrow} \mathsf{T}^{\mathrm{F}_{\sigma}} \longrightarrow 1,$$

where  $N_{\sigma}(t) = t \operatorname{F}_{\sigma}(t) \operatorname{F}_{\sigma}^{2}(t) \cdots \operatorname{F}_{\sigma}^{n-1}(t)$ . So  $N_{\sigma}$  induces an isomorphism

$$\operatorname{Hom}(\mathsf{T}^{\mathrm{F}_{\sigma}},\mathbb{C}^{\times}) \xrightarrow{\sim} \operatorname{Hom}_{\mathrm{F}_{\sigma},\mathrm{Id}}(\mathsf{T}^{\mathrm{F}_{\sigma}^{n}},\mathbb{C}^{\times}) = \operatorname{Hom}_{\mathrm{F}_{\sigma},\mathrm{Id}}(X \otimes \mathfrak{f}_{n}^{\times},\mathbb{C}^{\times}).$$

There is also an isomorphism

$$\operatorname{Hom}(\mathfrak{f}_n^{\times}, \hat{T}) \xrightarrow{\sim} \operatorname{Hom}(X \otimes \mathfrak{f}_n^{\times}, \mathbb{C}^{\times}), \quad s \mapsto \chi_s,$$

where  $\chi_s(\lambda \otimes a) = \lambda(s(a))$ , for  $\lambda \in X$ ,  $a \in \mathfrak{f}_n^{\times}$ . One checks that

$$\chi_s \in \operatorname{Hom}_{\mathcal{F}_{\sigma}, \operatorname{Id}}(X \otimes \mathfrak{f}_n^{\times}, \mathbb{C}^{\times}) \quad \Leftrightarrow \quad \hat{\sigma} \circ s = s \circ \operatorname{Frob},$$

where  $\hat{\sigma} \in \operatorname{Aut}(Y)$  is dual to  $\sigma$ . (The action of  $\hat{\sigma}$  on  $\hat{T}$  is such that  $\sigma \cdot \lambda = \lambda \circ \hat{\sigma}$  for all  $\lambda \in X$ .) Hence  $s \mapsto \chi_s$  is an isomorphism

$$\operatorname{Hom}_{\operatorname{Frob},\hat{\sigma}}(\mathfrak{f}_n^{\times},\hat{T}) \xrightarrow{\sim} \operatorname{Hom}_{\operatorname{F}_{\sigma},\operatorname{Id}}(X \otimes \mathfrak{f}_n^{\times}, \mathbb{C}^{\times})$$

The tame inertia group  $\mathcal{I}_t$  is identified with the projective limit

$$\mathcal{I}_t = \lim_{\stackrel{\leftarrow}{m}} \mathfrak{f}_m^{\times},$$

with respect to the norm mappings on the finite fields  $\mathfrak{f}_m$ . The canonical projection

$$\mathcal{I}_t \longrightarrow \mathfrak{f}_m^{\times}$$

induces an isomorphism as Frob-modules

$$\mathcal{I}_t/(1 - \operatorname{Ad} \operatorname{Frob}^m)\mathcal{I}_t \xrightarrow{\sim} \mathfrak{f}_m^{\times}.$$

Since  $\hat{\sigma}$  has order n, any  $s \in \operatorname{Hom}_{\operatorname{Ad}\operatorname{Frob},\hat{\sigma}}(\mathcal{I}_t, \hat{T})$  is trivial on  $(1 - \operatorname{Ad}\operatorname{Frob}^n)\mathcal{I}_t$ . It follows that

$$\operatorname{Hom}_{\operatorname{Frob},\hat{\sigma}}(\mathfrak{f}_n^{\times},\hat{T}) \simeq \operatorname{Hom}_{\operatorname{Ad}\operatorname{Frob},\hat{\sigma}}(\mathcal{I}_t,\hat{T}).$$

Thus the map  $s \mapsto \chi_s$  is a canonical bijection

$$\operatorname{Hom}_{\operatorname{Ad}\operatorname{Frob},\hat{\sigma}}(\mathcal{I}_t,\hat{T}) \xrightarrow{\sim} \operatorname{Hom}(\mathsf{T}^{\mathsf{F}_{\sigma}},\mathbb{C}^{\times}).$$

Now  $s \circ \text{Ad Frob} = \hat{\sigma} \circ s$  if and only if for some (equivalently, any)  $\tau \in \hat{T}$ , the assignment  $\text{Frob} \mapsto \hat{\sigma} \ltimes \tau$  extends s to a homomorphism

$$\varphi: \mathcal{W}_t \longrightarrow {}^L T_\sigma,$$

where  ${}^{L}T_{\sigma} = \langle \hat{\sigma} \rangle \ltimes \hat{T}$  is the *L*-group of the torus *T* with Frobenius  $F_{\sigma}$ . The  $\hat{T}$ -conjugacy class of the extension  $\varphi$  is uniquely determined by the image of  $\tau$  in  $\hat{T}/(1-\hat{\sigma})\hat{T}$ . The latter group is identified with the character group of  $X^{\sigma}$ , whereby  $\tau$  corresponds to

$$\chi_{\tau} \in \operatorname{Hom}(X^{\sigma}, \mathbb{C}^{\times}), \qquad \chi_{\tau}(\lambda) = \lambda(\tau).$$

Our choice of uniformizer in k gives an isomorphism

$$T^{\mathbf{F}_{\sigma}} \simeq {}^{0}T^{\mathbf{F}_{\sigma}} \times X^{\sigma},$$

where  ${}^{0}T$  is the group of  $R_{K}$ -points of **T**. Hence the above isomorphisms give a canonical bijection between  $\hat{T}$ -conjugacy classes of admissible homomorphisms  $\varphi : \mathcal{W}_{t} \longrightarrow {}^{L}T_{\sigma}$  and depth-zero characters

$$\chi_{\varphi} := \chi_s \otimes \chi_{\tau} \in \operatorname{Irr}(T^{\mathbf{F}_{\sigma}}),$$

where  $s = \varphi|_{\mathcal{I}_t}$  and  $\varphi(\text{Frob}) = \hat{\sigma} \ltimes \tau$ . This bijection has the following naturality property.

LEMMA 4.3.1. Let  $\alpha$  be an algebraic automorphism of T commuting with  $F_{\sigma}$ , so that  $\alpha \in Aut(X)$  and  $\hat{\alpha} \in Aut(Y)$ . Then  $\chi_{\varphi} \circ \alpha = \chi_{\hat{\alpha} \circ \varphi}$ .

*Proof.* We check it first on  $X^{\sigma}$ . Since  $\chi_{\varphi}(\mu) = \mu(\tau)$ , for  $\mu \in X^{\sigma}$ , we have

$$\chi_{\varphi}(\alpha \cdot \mu) = (\alpha \cdot \mu)(\tau) = \mu(\hat{\alpha} \cdot \tau) = \chi_{\hat{\alpha} \circ \varphi}(\mu).$$

Now on  $\mathsf{T}^{\mathsf{F}_{\sigma}}$  we have  $\chi_{\varphi} = \chi_s$ , where  $\chi_s \in \operatorname{Hom}_{\mathsf{F}_{\sigma},\operatorname{Id}}(X \otimes \mathfrak{f}_n^{\times}, \mathbb{C}^{\times})$ . For  $\lambda \in X$ ,  $a \in \mathfrak{f}_n^{\times}$ , we have

$$\chi_{\hat{\alpha}\circ\varphi}(\lambda\otimes a) = \chi_{\hat{\alpha}\circ s}(\lambda\otimes a) = \lambda(\hat{\alpha}\cdot(s(a)))$$
$$= (\alpha\cdot\lambda)(s(a)) = (\chi_s\circ\alpha)(\lambda\otimes a) = (\chi_\varphi\circ\alpha)(\lambda\otimes a).$$

Now let  $\varphi : \mathcal{W}_t \to {}^L G$  be a TRSELP, with associated  $w \in W_o$  and set  $\sigma = w\vartheta$ . We want to construct from  $\varphi$  a  $\hat{T}$ -conjugacy class of Langlands parameters

$$\varphi_T: \mathcal{W}_t \longrightarrow {}^L T_{\sigma_t}$$

such that  $\varphi_T = \varphi$  on  $\mathcal{I}$ , and such that  $\varphi_T(\text{Frob})$  and  $\varphi(\text{Frob})$  have the same action on  $\hat{T}$ . We will have

$$\varphi_T(\operatorname{Frob}) = \hat{\sigma} \ltimes \tau$$

for some  $\tau \in \hat{T}$ , which is only defined up to  $\hat{\sigma}$ -twisted conjugacy. That is, we need only define the coset of  $\tau$  in  $\hat{T}/(1-\hat{\sigma})\hat{T}$ .

We define the coset of  $\tau$  as follows. Let  $\hat{G}'$  be the derived group of  $\hat{G}$ , and let  $\hat{T}' = \hat{T} \cap \hat{G}'$ . Ellipticity implies that the map  $\tau \mapsto \tau \hat{\sigma}(\tau)^{-1}$  has finite kernel on  $\hat{T}'$ , which means that

$$(1 - \hat{\sigma})\hat{T}' = \hat{T}',$$

and so the inclusion  $\hat{T} \hookrightarrow \hat{G}$  induces a bijection

$$\hat{T}/(1-\hat{\sigma})\hat{T}' \xrightarrow{\sim} \hat{G}/\hat{G}' =: \hat{G}_{ab}.$$

It follows that  $\hat{T} \hookrightarrow \hat{G}$  induces a bijection

(16) 
$$\hat{T}/(1-\hat{\sigma})\hat{T} \xrightarrow{\sim} \hat{G}_{ab}/(1-\hat{\vartheta})\hat{G}_{ab}$$

between the set of  $\hat{\sigma}$ -twisted conjugacy classes in  $\hat{T}$  and the set of  $\hat{\vartheta}$ -twisted conjugacy classes in the abelianization  $\hat{G}_{ab}$ . Now, if  $\varphi(\text{Frob}) = \hat{\vartheta} \ltimes f$ , we take any  $\tau \in \hat{T}$  whose class in  $\hat{T}/(1-\hat{\sigma})\hat{T}$  corresponds under (16) to the image of f in  $\hat{G}_{ab}/(1-\hat{\vartheta})\hat{G}_{ab}$ .

Hence, from the TRSELP  $\varphi$  we get a character  $\chi_{\varphi_T} \in \operatorname{Irr}(T^{F_{\sigma}})$ . We will abuse notation slightly and again denote this character by  $\chi_{\varphi}$ .

4.4. From tame parameters to depth-zero types. Let  $\varphi : \mathcal{W}_t \longrightarrow {}^L G$  be a TRSELP with  $\varphi(\text{Frob}) = \hat{\vartheta}f$  as in Section 4.1. Let  $w \in W_o$  be the element such that  $\hat{w}$  is the image of f in  $\hat{W}_o$ . Since  $\varphi$  is elliptic, we have

(17) 
$$X^{w\vartheta} = X_* (\mathbf{Z}^\circ)^\vartheta, \qquad X^{w\vartheta}_{\mathrm{ad}} = \{0\},$$

where  $\mathbf{Z}^{\circ}$  is the identity component of the center  $\mathbf{Z}$  of  $\mathbf{G}$ .

Let  $\lambda \in X_w$ , and set

$$\sigma_{\lambda} = t_{\lambda} w \vartheta \in W \rtimes \langle \vartheta \rangle,$$

as in Section 2.7. By the second equation in (17), the operator  $I - w\vartheta$  acts invertibly on  $\mathcal{A}_{ad}$ , so that  $\sigma_{\lambda}$  has a unique fixed-point  $x_{\lambda} \in \mathcal{A}_{ad}$ , given by

$$x_{\lambda} = (I - w\vartheta)^{-1} t_{j\lambda} \cdot o.$$

Let  $\tilde{x}_{\lambda}$  be the pre-image of  $x_{\lambda}$  in  $\mathcal{A}^{\sigma_{\lambda}}$ .

829

The facet  $J_{\lambda}$  from Section 2.7 is the unique facet in  $\mathcal{A}$  containing  $\tilde{x}_{\lambda}$ . As in Section 2.7, we choose an alcove  $C_{\lambda}$  in  $\mathcal{A}$  containing  $J_{\lambda}$  in its closure, and write

$$G_{\lambda} := G_{J_{\lambda}}, \qquad W_{\lambda} := [N \cap G_{\lambda}]/{}^{0}T, \qquad \mathsf{G}_{\lambda} := G_{\lambda}/G_{\lambda}^{+}.$$

We choose  $u_{\lambda} \in Z^1(\mathbf{F}, N)$  as in Lemma 2.7.2, and define

$$F_{\lambda} := Ad(u_{\lambda}) \circ F$$
.

Then  $F_{\lambda}$  is a Frobenius endomorphism of G for some k-rational structure on **G** which is inner to the quasi-split structure on **G** given by F. Recall also that  $F_{\lambda}$  stabilizes the apartment  $\mathcal{A}$ , the alcove  $C_{\lambda}$ , and the facet  $J_{\lambda}$ .

LEMMA 4.4.1. We have

$$\mathcal{A}^{\sigma_{\lambda}} = J_{\lambda}^{\sigma_{\lambda}} = J_{\lambda}^{\mathbf{F}_{\lambda}} = \tilde{x}_{\lambda}.$$

In particular, the point  $x_{\lambda}$  is a vertex in  $\mathcal{B}(G_{\mathrm{ad}})^{\mathrm{F}_{\lambda}}$ .

*Proof.* From (7) of Section 2.7 we may decompose  $\sigma_{\lambda}$  in two ways:

$$\sigma_{\lambda} = t_{\lambda} w \vartheta = w_{\lambda} y_{\lambda} \vartheta.$$

Since  $w_{\lambda}$  fixes  $J_{\lambda}$  pointwise, we have

$$J_{\lambda}^{\mathbf{F}_{\lambda}} = J_{\lambda}^{y_{\lambda}\vartheta} = J_{\lambda}^{\sigma_{\lambda}} = \tilde{x}_{\lambda}.$$

Also,  $\mathcal{A}^{\sigma_{\lambda}} = \tilde{x}_{\lambda} \subseteq J_{\lambda}$ , implying that  $\mathcal{A}^{\sigma_{\lambda}} = J_{\lambda}^{\sigma_{\lambda}}$ .

Since  $F_{\lambda} \cdot J_{\lambda} = J_{\lambda}$ ,  $F_{\lambda}$  induces a Frobenius endomorphism of  $G_{\lambda}$ , preserving T. Since  $F_{\lambda} \cdot C_{\lambda} = C_{\lambda}$ , the Frobenius  $F_{\lambda}$  also preserves a Borel subgroup of  $G_{\lambda}$  containing T. It follows [6, 20.6] that T is a maximally f-split torus in  $G_{\lambda}$  with respect to  $F_{\lambda}$ .

From Section 2.7 we have the alternative expression

$$\sigma_{\lambda} = w_{\lambda} y_{\lambda} \vartheta,$$

where  $w_{\lambda} \in W_{\lambda}$  and  $y_{\lambda}$  is the image of  $u_{\lambda}$  in W. Moreover, our fixed choice of lift  $\dot{w}$  of w defines a lift  $\dot{w}_{\lambda} \in N \cap G_{\lambda}$  of  $w_{\lambda}$ , via the equation

$$t_{\lambda}\dot{w} = \dot{w}_{\lambda}u_{\lambda}.$$

Recall that we can then choose an element  $p_{\lambda} \in G_{\lambda}$  such that

$$p_{\lambda}^{-1} \mathbf{F}_{\lambda}(p_{\lambda}) = \dot{w}_{\lambda}$$

Note that

$$F_{\lambda} \circ \operatorname{Ad}(p_{\lambda}) = \operatorname{Ad}(p_{\lambda}) \circ \operatorname{Ad}(\dot{w}_{\lambda}u_{\lambda}) \circ F$$

Define

$$T_{\lambda} := \operatorname{Ad}(p_{\lambda})T.$$

Then  $T_{\lambda}$  is an  $F_{\lambda}$ -stable unramified torus in G. On T, we have  $\operatorname{Ad}(\dot{w}_{\lambda}u_{\lambda}) = \operatorname{Ad}(w)$ , so that  $\operatorname{Ad}(p_{\lambda}) : T \longrightarrow T_{\lambda}$  satisfies

$$F_{\lambda} \circ \operatorname{Ad}(p_{\lambda}) = \operatorname{Ad}(p_{\lambda}) \circ F_{w},$$

where  $F_w = Ad(\dot{w}) \circ F$ .

By ellipticity, we have

$$T^{\mathbf{F}_w} = X^{w\vartheta} \times {}^0T^{\mathbf{F}_w} = X_*(\mathbf{Z}^\circ)^\vartheta \times {}^0T^{\mathbf{F}_w} = Z^{\mathbf{F}} \cdot {}^0T^{\mathbf{F}_w}.$$

This implies that  $T_{\lambda}$  is  $F_{\lambda}$ -minisotropic. Moreover, we have  ${}^{0}T_{\lambda} = T_{\lambda} \cap G_{\lambda}$ , and  ${}^{0}T_{\lambda}$  projects to an  $F_{\lambda}$ -minisotropic maximal torus  $\mathsf{T}_{\lambda}$  in  $\mathsf{G}_{\lambda}$ .

On  $\mathcal{A}$  and  $\mathcal{A}_{ad}$  we have  $\operatorname{Ad}(\dot{w}_{\lambda}u_{\lambda}) \operatorname{F} = \sigma_{\lambda}$ . By Lemma 4.4.1 the unique fixed-point of  $T_{\lambda}$  in  $\mathcal{B}(G_{ad})^{\operatorname{F}_{\lambda}}$  is

$$[p_{\lambda} \cdot \mathcal{A}_{\mathrm{ad}}]^{\mathrm{F}_{\lambda}} = p_{\lambda} \cdot \mathcal{A}_{\mathrm{ad}}^{\sigma_{\lambda}} = p_{\lambda} \cdot x_{\lambda} = x_{\lambda}.$$

As in Section 4.3, we have a depth-zero character  $\chi = \chi_{\varphi}$  of  $T^{F_w}$ . Since  $\varphi$  is in general position, Lemma 4.3.1 implies that  $\chi$  is  $F_w$ -regular.

This character  $\chi$  transports to a depth-zero  $F_{\lambda}$ -regular character

$$\chi_{\lambda} := \operatorname{Ad}(p_{\lambda})_* \chi \in \operatorname{Irr}(T_{\lambda}^{\mathrm{F}_{\lambda}}).$$

The restriction of  $\chi_{\lambda}$  to  ${}^{0}T_{\lambda}^{F_{\lambda}}$  factors through a character  $\chi_{\lambda}^{0} \in \operatorname{Irr}(\mathsf{T}_{\lambda}^{F_{\lambda}})$ , which is in "general position" with respect to  $F_{\lambda}$ , in the sense of [20, 5.16]. By [20, 8.3], Deligne-Lusztig induction then gives an irreducible cuspidal representation

$$\kappa_{\lambda}^{0} := \epsilon(\mathsf{G}_{\lambda}, \mathsf{T}_{\lambda}) \cdot R_{\mathsf{T}_{\lambda}, \chi_{\lambda}^{0}}^{\mathsf{G}_{\lambda}} \in \operatorname{Irr}(\mathsf{G}_{\lambda}^{\mathrm{F}_{\lambda}}).$$

Inflate  $\kappa^0_{\lambda}$  to a representation of  $G^{\mathcal{F}_{\lambda}}_{\lambda}$  and define an extension to  $Z^{\mathcal{F}}G^{\mathcal{F}_{\lambda}}_{\lambda}$  by

$$\kappa_{\lambda} := \chi_{\lambda} \otimes \kappa_{\lambda}^0.$$

This makes sense since  $(Z \cap G_{\lambda})^{F_{\lambda}}$  acts on  $\kappa_{\lambda}^{0}$  via the restriction of the scalar character  $\chi_{\lambda}^{0}$ .

So far, to the TRSELP  $\varphi$  and  $\lambda \in X_w$ , we have associated a Frobenius  $F_{\lambda}$ , an  $F_{\lambda}$ -stable parahoric subgroup  $G_{\lambda}$ , and an irreducible representation  $\kappa_{\lambda}$  of  $Z^{\mathrm{F}}G_{\lambda}^{F_{\lambda}}$ . In the process we made choices of  $\dot{w}, C_{\lambda}, u_{\lambda}, p_{\lambda}$ .

LEMMA 4.4.2. Given a TRSELP  $\varphi$  and  $\lambda \in X_w$ , both fixed, suppose there are two sets of choices  $(\dot{w}, C_{\lambda}, u_{\lambda}, p_{\lambda})$  and  $(\dot{w}', C'_{\lambda}, u'_{\lambda}, p'_{\lambda})$  as above, giving rise to  $(F_{\lambda}, T_{\lambda}, \chi_{\lambda}, \kappa_{\lambda})$  and  $(F'_{\lambda}, T'_{\lambda}, \chi'_{\lambda}, \kappa'_{\lambda})$  as above. Then there is  $h \in G_{\lambda}$  such that

- (1)  $h * u'_{\lambda} = u_{\lambda};$
- (2)  $\operatorname{Ad}(h)_*(T'_{\lambda}, \chi'_{\lambda}, \kappa'_{\lambda}) = (T_{\lambda}, \chi_{\lambda}, \kappa_{\lambda}).$

*Proof.* Note that (1) implies that  $\operatorname{Ad}(h)(G_{\lambda}^{\mathbf{F}_{\lambda}'}) = G_{\lambda}^{\mathbf{F}_{\lambda}}$ , so that (2) makes sense. Since  $\sigma_{\lambda}$  is defined before the choices are made, we have

$$w_{\lambda}y_{\lambda} = t_{\lambda}w = w_{\lambda}'y_{\lambda}'$$

and so there is  $t \in {}^{0}T$  such that

$$\dot{w}_{\lambda}u_{\lambda} = t\dot{w}_{\lambda}'u_{\lambda}'.$$

Here, both sides belong to  $Z^1(\mathbf{F}, N)$  and act on T via w. Lemma 2.1.1 implies that  $t \in Z^1(\mathbf{F}_w, {}^0T)$ . By Lemma 2.3.1 for  ${}^0T$ , there is  $s \in {}^0T$  such that

(18) 
$$s F_w(s)^{-1} = t$$

Since  $\operatorname{Ad}(w) = \operatorname{Ad}(\dot{w}'_{\lambda}u'_{\lambda})$  on T, equation (18) can be written

(19) 
$$s\dot{w}'_{\lambda}u'_{\lambda} = t\dot{w}'_{\lambda}u'_{\lambda}F(s) = \dot{w}_{\lambda}u_{\lambda}F(s)$$

Recall our equations characterizing  $p_{\lambda}$  and  $p'_{\lambda}$ :

(20) 
$$p_{\lambda}^{-1} \mathbf{F}_{\lambda}(p_{\lambda}) = \dot{w}_{\lambda}, \qquad p_{\lambda}'^{-1} \mathbf{F}_{\lambda}'(p_{\lambda}') = \dot{w}_{\lambda}'.$$

These allow us to write (19) in the form

(21) 
$$s \cdot p_{\lambda}^{\prime -1} u_{\lambda}^{\prime} \operatorname{F}(p_{\lambda}^{\prime}) = p_{\lambda}^{-1} u_{\lambda} \operatorname{F}(p_{\lambda}) \cdot \operatorname{F}(s).$$

Equation (21) shows that the element  $h := p_{\lambda} s {p'_{\lambda}}^{-1}$  satisfies  $h * u'_{\lambda} = u_{\lambda}$ . We have  $h \in G_{\lambda}$  since  $p_{\lambda}, s, p'_{\lambda}$  are all in  $G_{\lambda}$ . It is clear that  $\mathrm{Ad}(h)(T'_{\lambda}, \chi'_{\lambda}) = (T_{\lambda}, \chi_{\lambda})$ , which then implies that  $\mathrm{Ad}(h)_* \kappa'_{\lambda} = \kappa_{\lambda}$ .

4.5. Definition of the L-packets. Given a TRSELP  $\varphi$ , an element  $\lambda \in X_w$ and a set of choices  $(C_{\lambda}, u_{\lambda}, p_{\lambda})$ , define

$$\pi_{\lambda} := \operatorname{Ind}_{Z^{\mathrm{F}}G_{\lambda}^{\mathrm{F}_{\lambda}}}^{G^{\mathrm{F}_{\lambda}}} \kappa_{\lambda},$$

where Ind denotes smooth induction. (The functions in  $\pi_{\lambda}$  automatically have compact support modulo  $Z^F$ .) In this notation we have suppressed the choices  $(C_{\lambda}, u_{\lambda}, p_{\lambda})$ , but by Lemma 4.4.2 the *G*-orbit (in fact the  $G_{\lambda}$ -orbit) of  $(u_{\lambda}, \pi_{\lambda})$ is independent of these choices.

LEMMA 4.5.1. The representation  $\pi_{\lambda}$  of  $G^{F_{\lambda}}$  is irreducible supercuspidal.

*Proof.* By [44, 6.6] it suffices to show that  $\kappa_{\lambda}$  induces irreducibly to the group

$$(G_{\lambda}^{\star})^{\mathbf{F}_{\lambda}} = \{g \in G^{\mathbf{F}_{\lambda}} : g \cdot J_{\lambda} = J_{\lambda}\},\$$

which is the normalizer of  $G_{\lambda}^{F_{\lambda}}$  in  $G^{F_{\lambda}}$ . For this, it is enough to show the stabilizer of  $\kappa_{\lambda}$  in  $(G_{\lambda}^{\star})^{F_{\lambda}}$  is just  $Z^{F_{\lambda}}G_{\lambda}^{F_{\lambda}}$ .

Suppose  $h \in (G_{\lambda}^{\star})^{F_{\lambda}}$  and  $\operatorname{Ad}(h)_{*}\kappa_{\lambda} = \kappa_{\lambda}$ . By [20, Thm. 6.8], there is  $g \in G_{\lambda}^{F_{\lambda}}$  such that

$$\operatorname{Ad}(gh)_*(\mathsf{T}_\lambda,\chi_\lambda) = (\mathsf{T}_\lambda,\chi_\lambda).$$

Then by [14] there is  $\ell \in (G_{\lambda}^+)^{F_{\lambda}}$  such that

$$\operatorname{Ad}(\ell gh)_*(T_\lambda,\chi_\lambda) = (T_\lambda,\chi_\lambda).$$

That is,  $\ell gh \in N(G, T_{\lambda})^{F_{\lambda}}$  and fixes  $\chi_{\lambda}$ . Hence  $p_{\lambda}^{-1}\ell ghp_{\lambda} \in N^{F_{w}}$  and fixes  $\chi$ . Let z be the projection of  $p_{\lambda}^{-1}\ell ghp_{\lambda}$  to  $W_{o}$ . By Lemma 4.3.1 we have  $\hat{z} \circ s = s$ , but  $C_{\hat{G}}(s) = \hat{T}$ , so z = 1. It follows that  $\ell gh \in T_{\lambda}^{F_{\lambda}} \cap (G_{\lambda}^{\star})^{F_{\lambda}} \subset Z^{F_{\lambda}}G_{\lambda}^{F_{\lambda}}$ . Since  $\ell$  and g are in  $G_{\lambda}^{F_{\lambda}}$ , this implies that  $h \in Z^{F_{\lambda}}G_{\lambda}^{F_{\lambda}}$ .

At this point we have a supercuspidal representation  $\pi_{\lambda} \in \operatorname{Irr}(G^{F_{\lambda}})$  for every  $\lambda \in X_w$ . We now show that the *G*-orbit  $[u_{\lambda}, \pi_{\lambda}] := \operatorname{Ad}(G) \cdot (u_{\lambda}, \pi_{\lambda})$ depends only on the character  $\rho_{\lambda} \in \operatorname{Irr}(C_{\varphi})$  corresponding to the image of  $\lambda$ in  $[X/(1-w\vartheta)X]_{\operatorname{tor}} = \operatorname{Irr}(C_{\varphi})$  (see §4.1).

LEMMA 4.5.2. Given  $\varphi$ , along with  $\lambda, \mu \in X_w$ , make choices  $(C_\lambda, u_\lambda, p_\lambda)$ ,  $(C_\mu, u_\mu, p_\mu)$  as above. Then  $\rho_\lambda = \rho_\mu$  if and only if there exists  $g \in G$  such that

(1)  $g * u_{\lambda} = u_{\mu};$ (2)  $g \cdot J_{\lambda} = J_{\mu};$ (3)  $\operatorname{Ad}(g)_{*}\kappa_{\lambda} \simeq \kappa_{\mu}.$ 

*Proof.* Suppose  $\rho_{\lambda} = \rho_{\mu}$ . This is equivalent to having  $\mu = \lambda + (1 - w\vartheta)\nu$  for some  $\nu \in X$ , which amounts to the following equation in  $W \rtimes \langle \vartheta \rangle$ :

$$t_{\nu}\sigma_{\lambda}t_{\nu}^{-1} = t_{\nu}t_{\lambda}w\vartheta t_{\nu}^{-1} = t_{\mu}w\vartheta = \sigma_{\mu}.$$

Lifting to N, we have

(22) 
$$t_{\nu}\dot{w}_{\lambda}u_{\lambda}\operatorname{F}(t_{\nu})^{-1} = t\dot{w}_{\mu}u_{\mu}$$

for some  $t \in {}^{0}T$ . Arguing as in the proof of Lemma 4.4.2, there is  $s \in {}^{0}T_{\mu}$  such that

$$p_{\mu}tp_{\mu}^{-1} = s^{-1} F_{\mu}(s).$$

Using Equations (20) we then find that

$$g * u_{\lambda} = u_{\mu},$$

where  $g = sp_{\mu}t_{\nu}p_{\lambda}^{-1}$ .

Since  $\sigma_{\lambda}$  and  $\sigma_{\mu}$  have unique fixed-points  $x_{\lambda}$  and  $x_{\mu}$  in  $\mathcal{A}_{ad}$ , we must have  $t_{\nu} \cdot x_{\lambda} = x_{\mu}$ , hence  $t_{\nu} \cdot J_{\lambda} = J_{\mu}$ , from which (2) is immediate.

Finally, we have

$$\operatorname{Ad}(g)_*(T_\lambda, \chi_\lambda) = \operatorname{Ad}(sp_\mu t_\nu)_*(T, \chi) = \operatorname{Ad}(s)_*(T_\mu, \chi_\mu)_*(T, \chi)$$

so that  $\operatorname{Ad}(g)_*\kappa_\lambda \simeq \kappa_\mu$ .

Turning to the converse, suppose we have  $g \in G$  satisfying items (1)–(3) above. By (2) and (3) and [20, Thm. 6.8], the pairs

$$(\operatorname{Ad}(g)T_{\lambda}, \operatorname{Ad}(g)_{*}\chi_{\lambda}), \qquad (T_{\mu}, \chi_{\mu})$$

are conjugate in  $G_{\mu}^{F_{\mu}}$ , and so without loss of generality, we may assume these two pairs are equal. Then, the element  $n := p_{\mu}^{-1}gp_{\lambda}$  belongs to N. By (1), Ad(n) preserves  $T^{F_w}$ , and it preserves the  $F_w$ -regular character  $\chi$ , since Ad(g)<sub>\*</sub> $\chi_{\lambda} = \chi_{\mu}$ . It follows that  $n \in T$ . Let  $t_{\nu}$  be the image of n in W. As in the first paragraph of the proof, it suffices to prove that  $t_{\nu}\sigma_{\lambda}t_{\nu}^{-1} = \sigma_{\mu}$ . But this follows from the equation

$$\operatorname{Ad}(n) \circ \operatorname{Ad}(\dot{w}_{\lambda}u_{\lambda}) \circ F \circ \operatorname{Ad}(n)^{-1} = \operatorname{Ad}(\dot{w}_{\mu}u_{\mu}) \circ F,$$

which is proved using Equations (20) as before.

Now we have our first main result.

THEOREM 4.5.3. Given a TRSELP  $\varphi$  with associated  $w \in W_o$ , let  $r: X_w \to H^1(\mathbf{F}, G)$  be as in Section 2.8. For each  $\omega \in H^1(\mathbf{F}, G)$  define

$$\Pi(\varphi,\omega) := \{ [u_{\lambda}, \pi_{\lambda}] : \lambda \in r^{-1}(\omega) \}.$$

Then there is a well-defined bijection  $\operatorname{Irr}(C_{\varphi}, \omega) \xrightarrow{\sim} \Pi(\varphi, \omega)$ , as follows. Given  $\rho \in \operatorname{Irr}(C_{\varphi}, \omega)$ , choose any  $\lambda \in r^{-1}(\omega)$  such that  $\rho_{\lambda} = \rho$ , and associate to  $\rho$  the G-orbit  $[u_{\lambda}, \pi_{\lambda}] \in \Pi(\varphi, \omega)$ .

*Proof.* Recall that  $r(\lambda) = \omega$  if and only if  $\rho_{\lambda} \in \operatorname{Irr}(\varphi, \omega)$ . Suppose we have  $\lambda, \mu \in X_w$  such that  $\rho_{\lambda}, \rho_{\mu} \in \operatorname{Irr}(\varphi, \omega)$ . From [44, 6.2] it follows that conditions 1–3 of Lemma 4.5.2 are equivalent to having  $g \in G$  such that

$$\operatorname{Ad}(g) \cdot (u_{\lambda}, \pi_{\lambda}) = (u_{\mu}, \pi_{\mu}).$$

So we have proved that

$$[u_{\lambda}, \pi_{\lambda}] = [u_{\mu}, \pi_{\mu}] \quad \Leftrightarrow \quad \rho_{\lambda} = \rho_{\mu},$$

as desired.

Remark 4.5.4. Recall that  $Irr(C_{\varphi}, \omega)$  is equal to the fiber over  $\omega$  under the composition

$$\operatorname{Irr}(C_{\varphi}) \xrightarrow{\sim} \left[ X/(1-w\vartheta)X \right]_{\operatorname{tor}} \to \left[ \bar{X}/(1-\vartheta)\bar{X} \right]_{\operatorname{tor}} \xrightarrow{\sim} H^{1}(\mathbf{F},G),$$

whereby  $\rho = \rho_{\lambda} \mapsto r(\lambda)$ . By Lemma 2.7.3 we have  $u_{\lambda} \in \omega_{\lambda} = r(\lambda) = \omega$ . Hence our representation  $\pi_{\lambda}$  lives on an inner twist of G belonging to the class  $\omega \in H^1(\mathbf{F}, G)$ , in accordance with the conjectures in Section 3.

4.6. Choosing representatives in an L-packet. We now use Section 2.8 to choose representatives, living on a single group, of each G-orbit in an L-packet  $\Pi(\varphi, \omega)$ . We fix  $u \in \omega \cap N$ , and for each  $\lambda \in r^{-1}(\omega)$  we choose  $m_{\lambda}$  as in Section 2.8. For each  $\rho \in \operatorname{Irr}(C_{\varphi}, \omega)$ , define

$$\pi_u(\varphi, \rho) := \operatorname{Ad}(m_\lambda)_* \pi_\lambda \in \operatorname{Irr}(G^{\mathcal{F}_u}),$$

for any  $\lambda \in r^{-1}(\omega)$  such that  $\rho_{\lambda} = \rho$ . We have seen that the isomorphism class of  $\pi_{\lambda}$  is independent of the choice of  $\lambda$ . Two choices of  $m_{\lambda}$  differ by an element of  $G^{F_u}$ , so the isomorphism class of  $\pi_u(\varphi, \rho_{\lambda})$  likewise does not depend on the choice of  $m_{\lambda}$ . The normalized *L*-packet is then defined as

$$\Pi_u(\varphi) := \{ \pi_u(\varphi, \rho) : \rho \in \operatorname{Irr}(C_{\varphi}, \omega) \}.$$

More explicitly, the representation  $\pi_u(\varphi, \rho)$  is given as follows. Recall that  $m_{\lambda} \cdot C_{\lambda}$  is our fixed  $F_u$ -stable alcove C. The facet  $I_{\lambda} := m_{\lambda} \cdot J_{\lambda}$  is contained in  $\overline{C}$ , and is likewise  $F_u$ -stable. The  $F_u$ -minisotropic torus  $S_{\lambda} = \operatorname{Ad}(m_{\lambda})T_{\lambda} = \operatorname{Ad}(q_{\lambda})T$  (see §2.8) has the property that  $S_{\lambda} \cap G_{I_{\lambda}}$  projects to an  $F_u$ -minisotropic torus  $S_{\lambda}$  in  $G_{I_{\lambda}}$ . The character  $\theta_{\lambda} := \operatorname{Ad}(m_{\lambda})_*\chi_{\lambda} = \operatorname{Ad}(q_{\lambda})_*\chi$  is  $F_u$ -regular, and gives a(n inflated) Deligne-Lusztig representation

$$\varkappa_{\lambda}^{0} := \varepsilon(\mathsf{G}_{I_{\lambda}}, \mathsf{S}_{\lambda}) \cdot R_{\mathsf{S}_{\lambda}, \theta_{\lambda}}^{\mathsf{G}_{I_{\lambda}}} \in \operatorname{Irr}(G_{I_{\lambda}}^{\operatorname{F}_{u}}),$$

and an extension of  $\varkappa_{\lambda}^{0}$  to a representation  $\varkappa_{\lambda}$  of  $Z^{F}G_{I_{\lambda}}^{F_{u}}$ . Finally, we have

$$\pi_u(\varphi,\rho) = \operatorname{Ind}_{Z^F G_{I_\lambda}^{\operatorname{F}_u}}^{G^{\operatorname{F}_u}} \varkappa_\lambda$$

## 5. Normalizations of measures and formal degrees

We now move toward Harmonic Analysis. The first step is a uniform normalization of Haar measures on groups of the form  $G^F$ , where  $G = \mathbf{G}(K)$  and  $\mathbf{G}$  is a connected reductive k-group, split over K. We then verify the equality of formal degrees in an L-packet, according to the conjectures in Section 3. (Note that the group  $C_{\varphi}$  is abelian for these L-packets.) Except where noted, our Frobenius on G is now unspecified, and is denoted by F, according to our conventions.

5.1. *Haar measure.* We denote the Lie algebra of G by  $\mathfrak{g}$ , and again let F denote the induced Frobenius action on  $\mathfrak{g}$ .

Suppose  $x \in \mathcal{B}(G)$  or  $\mathcal{B}(G_{ad})$ . Just as we could attach a parahoric  $G_x$ and its pro-unipotent radical  $G_x^+$  to x, so we can define lattices  $\mathfrak{g}_x$  and  $\mathfrak{g}_x^+$  in  $\mathfrak{g}$ (see [43, §3.2], [3, §2.2], where the corresponding objects are called  $\mathfrak{g}_{x,0}$  and  $\mathfrak{g}_{x,0^+}$ ). As before, the lattices  $\mathfrak{g}_x$  and  $\mathfrak{g}_x^+$  are independent of the facet to which x belongs. If J is any subset of a facet and  $x \in J$ , then we set  $\mathfrak{g}_J = \mathfrak{g}_x$  and  $\mathfrak{g}_J^+ = \mathfrak{g}_x^+$ . If J is an F-stable subset of a facet, then

$$\mathsf{L}_J := \mathfrak{g}_J/\mathfrak{g}_J^+$$

is the Lie algebra of  $G_J$ , and we have

$$\mathsf{L}_J^F = \mathfrak{g}_J^F / (\mathfrak{g}_J^{+F}).$$

Let dg denote the Haar measure on  $G^F$ , normalized so that

$$\operatorname{meas}_{dg}(G_J^F) = \frac{|\mathsf{G}_J^F|}{|\mathsf{L}_J^F|^{1/2}}$$

for one, in fact every, F-stable facet J in  $\mathcal{B}(G)$ .

Let dX denote the Haar measure on  $\mathfrak{g}^F$ , normalized so that

$$\operatorname{meas}_{dX}(\mathfrak{g}_J^F) = |\mathsf{L}_J^F|^{1/2}$$

for one (in fact, every) F-stable facet J in  $\mathcal{B}(G)$ .

To show that these normalizations are independent of the choice of J as claimed, it is enough to show that if J and J' are F-stable facets in  $\mathcal{B}(G)$  with  $J' \subset \overline{J}$ , then

$$\operatorname{meas}_{dg}(G_J^F) = \frac{\left|\mathsf{G}_J^F\right|}{|\mathsf{L}_J^F|^{1/2}}$$

implies

$$\operatorname{meas}_{dg}(G_{J'}^F) = \frac{\left|\mathsf{G}_{J'}^F\right|}{|\mathsf{L}_{J'}^F|^{1/2}}$$

(and similarly for the measure dX on  $\mathfrak{g}$ ). Since  $J' \subset \overline{J}$ , we have

$$G_{J'}^+ \subset G_J^+ \subset G_J \subset G_{J'}.$$

Moreover, the image of  $G_J$  in  $\mathsf{G}_{J'}$  is a parabolic f-subgroup with unipotent radical  $G_J^+/G_{J'}^+$  and Levi component isomorphic to  $\mathsf{G}_J$ . A short calculation gives the desired result.

Remark 5.1.1. The above expression for  $\operatorname{meas}_{dg}(G_J^F)$  can be simplified a bit. Let  $\mathsf{G}$  be a connected reductive group over  $\mathfrak{f}$  with Frobenius F. Let  $\mathsf{T} \subset \mathsf{B}$  be an F-stable maximal torus and an F-stable Borel subgroup in  $\mathsf{G}$ . Then

$$|\mathsf{G}^F| = [\mathsf{G}^F : \mathsf{B}^F] \cdot |\mathsf{B}^F| = q^{\nu}[\mathsf{G}^F : \mathsf{B}^F] \cdot |\mathsf{T}^F|,$$

where  $\nu$  is the number of (absolute) roots of T in B. The latter two factors are prime to p, so that

$$|\mathsf{G}^F|_{p'} = [\mathsf{G}^F : \mathsf{B}^F] \cdot |\mathsf{T}^F|,$$

where  $|\cdot|_{p'}$  is the largest factor of  $|\cdot|$  which is prime to p. We have dim  $G = \dim T + 2\nu$ . It follows that

$$\operatorname{meas}_{dg}(G_J^F) = q^{-\operatorname{rk}(\mathbf{G})/2} |\mathsf{G}_J^F|_{p'}.$$

where  $rk(\mathbf{G})$  is the absolute rank of  $\mathbf{G}$ .

This normalization applies as well to the largest k-split torus  $\mathbf{Z}$  of the center of  $\mathbf{G}$ , and gives

$$\operatorname{meas}_{dz}({}^{0}Z^{F}) = q^{-\operatorname{rk}(\mathbf{Z})/2} |\mathsf{Z}^{F}| = (q^{1/2} - q^{-1/2})^{\operatorname{rk}(\mathbf{Z})},$$

where  $\mathsf{Z} = {}^0Z/{}^0Z^+$ .

For any irreducible admissible representation  $\pi$  of  $G^F$  which is squareintegrable modulo  $Z^F$ , let  $\text{Deg}(\pi)$  denote the formal degree of  $\pi$  with respect to the quotient measure dg/dz on  $G^F/Z^F$  (cf. [26]).

5.2. Formal degree of the Steinberg representations. The formal degree conjectures in Section 3 require Haar measures for which the formal degree of the Steinberg representation of  $G^F$  is unchanged by inner twists of F, for  $F = F_u$ . In this section we show that the measures dg defined above have this property. First we consider some constants arising in this formal degree.

Recall that the quasi-split Frobenius F acts on  $X = X_*(\mathbf{T})$  by the automorphism  $\vartheta$ , and that  $\mathbf{Z}$  denotes the largest k-split torus in the center of  $\mathbf{G}$ . Note that  $G/Z = (\mathbf{G}/\mathbf{Z})^{\mathcal{I}}$ .

Let  $X_1 = X_*(\mathbf{T}/\mathbf{Z})$  and let  $C_1$  be the projection to the apartment of T/Zin  $\mathcal{B}(G/Z)$  of the  $\vartheta$ -stable alcove C in  $\mathcal{A}$ . Let  $\Omega_1$  be the stabilizer of  $C_1$  in the affine Weyl group of T/Z in G/Z. The inclusion  $X_*(\mathbf{Z}) \hookrightarrow X$  projects to an embedding

$$X_*(\mathbf{Z}) \hookrightarrow (X/X^\circ)^\vartheta \simeq \Omega_C^\vartheta$$

where  $X^{\circ}$  is the co-root lattice of **T**. Identifying, as we may,  $X^{\circ}$  with the co-root lattice of **T**/**Z**, we have

$$\Omega_1 \simeq X_1 / X^\circ \simeq \Omega_C / X_*(\mathbf{Z}),$$

and a finite subgroup  $\Omega_2 := \Omega_C^{\vartheta} / X_*(\mathbf{Z}) \hookrightarrow \Omega_1$  fitting into the exact sequence

$$1 \longrightarrow \Omega_2 \longrightarrow \Omega_1 \xrightarrow{1-\vartheta} \Omega_1 \longrightarrow \Omega_1/(1-\vartheta)\Omega_1 \longrightarrow 1,$$

showing that

(23) 
$$|\Omega_2| = |\Omega_1/(1-\vartheta)\Omega_1| = |H^1(\mathbf{F}, G/Z)|$$

Now take a cocycle  $u \in Z^1(\mathbf{F}, N_C)$ , with corresponding twist  $\mathbf{F}_u = \mathrm{Ad}(u) \circ \mathbf{F}$ as before. Since  $u \in N_C$  and  $\Omega_C$  is abelian, we have  $\Omega_C^{u\vartheta} = \Omega_C^\vartheta$ . It follows that  $\Omega_2$  is unchanged if we replace  $\vartheta$  by an inner twist  $u\vartheta$ . Of course this also follows from (23).

Next, let  $V_1 = X_1 \otimes \mathbb{C}$ , let R be the graded  $\mathbb{C}$ -algebra of  $W_o$ -invariant polynomial functions on the  $\mathbb{C}$ -vector space  $V_1$ , and let  $\mathfrak{m}$  be the maximal ideal in R of functions vanishing at  $0 \in V_1$ . Then  $V := \mathfrak{m}/\mathfrak{m}^2$  is a vector space of dimension  $\ell := \dim V_1$ . The space V inherits a grading from R, written  $V = \oplus V(d)$ . Moreover,  $\vartheta$  acts naturally on R and V, preserving the grading. Choose a basis of eigenvectors for  $\vartheta$  in each V(d) and let  $f_1, \ldots, f_\ell$ be the collection of eigenvectors obtained. Let  $d_j = \deg(f_j)$  and let  $\epsilon_j$  be the eigenvalue of  $\vartheta$  on  $f_j$ .

Define the constant

$$c(\mathbf{G}/\mathbf{Z}) := |\Omega_2| \cdot \prod_{i=1}^{\ell} \frac{q^{d_i} - \epsilon_i}{q^{d_i - 1} - \epsilon_i}.$$

The denominators in  $c(\mathbf{G}/\mathbf{Z})$  are nonzero because each  $\epsilon_i$  is a root of unity and  $V(1)^{\vartheta} = \{0\}$ . Since *u* acts trivially on *R* and  $|\Omega_2|$  is invariant under inner-twists, it follows that  $c(\mathbf{G}/\mathbf{Z})$  is invariant under inner-twists.

Let  $G_{C_1}$  be the Iwahori subgroup of G/Z at the alcove  $C_1$ . From [5, 5.3] and [55, 3.10], (see also [22, 5.5]) it follows that the formal degree of the Steinberg representation  $\operatorname{St}_u$  of  $G^{\operatorname{F}_u}$  is given, using our normalizations in Section 5.1, by

$$\begin{aligned} \operatorname{Deg}(\operatorname{St}_{u}) &= \frac{|\mathsf{T}^{\operatorname{F}_{u}}/\mathsf{Z}^{\operatorname{F}_{u}}|}{c(\mathbf{G}/\mathbf{Z})} \cdot \frac{1}{\operatorname{meas}_{dg/dz}(G_{C_{1}}^{\operatorname{F}_{u}})} \\ &= \frac{|\mathsf{G}_{C_{1}}^{\operatorname{F}_{u}}|_{p'}}{c(\mathbf{G}/\mathbf{Z})} \cdot \frac{q^{\operatorname{rk}(\mathbf{G}/\mathbf{Z})/2}}{|\mathsf{G}_{C_{1}}^{\operatorname{F}_{u}}|_{p'}} \\ &= \frac{q^{\operatorname{rk}(\mathbf{G}/\mathbf{Z})/2}}{c(\mathbf{G}/\mathbf{Z})}. \end{aligned}$$

This last expression is independent of u, as claimed.

5.3. Formal degrees in our L-packets. Now suppose  $\pi$  is an irreducible cuspidal representation of  $G^F$  of the sort considered in 4.5, namely  $\pi = \operatorname{Ind}_{G_J^F Z^F}^{G^F} \kappa$ , for some minimal F-stable facet  $J \subset \mathcal{B}(G)$  and  $\kappa \in \operatorname{Irr}(G_J^F Z^F)$ . The formal degree of  $\pi$  is given by

$$\operatorname{Deg}(\pi) = \dim \kappa \cdot \frac{\operatorname{meas}_{dz}({}^{0}Z^{F})}{\operatorname{meas}_{dg}(G_{J}^{F})}.$$

Recall also that  $\kappa$  is of the following form. We have an F-minisotropic torus S < G such that  $\mathcal{A}(S)^F = J^F$ , a regular character  $\theta \in \operatorname{Irr}(S^F)$  whose restriction to  $S \cap G_J^F$  factors through  $\mathsf{S}^F = S \cap G^F / S \cap G_J^{+F}$ , and on  $G_J^F$ ,

$$\kappa = \varepsilon(\mathsf{G}_J, \mathsf{S}) \cdot R_{\mathsf{S},\theta}^{\mathsf{G}_J}.$$

By [20, Thm. 7.1],

$$\dim \kappa = \frac{|\mathsf{G}_J^F|_{p'}}{|\mathsf{S}^F|}.$$

Using also Remark 5.1.1, we find that

$$\operatorname{Deg}(\pi) = \frac{|\mathsf{Z}^F|}{|\mathsf{S}^F|} q^{\operatorname{rk}(\mathbf{G}/\mathbf{Z})/2}.$$

Now if  $F = F_u$  and  $\pi = \pi_u(\varphi, \rho)$  as in 4.6, then the torus S is k-isomorphic to the platonic torus T with twisted Frobenius  $F_w$  (see 2.8). Therefore, we have

$$\operatorname{Deg}(\pi_u(\varphi,\rho)) = \frac{q^{\operatorname{rk}(\mathbf{G}/\mathbf{Z})/2}}{|\mathsf{T}^{\mathrm{F}_w}/\mathsf{Z}^{\mathrm{F}}|}$$

The right side of this equation is independent of u and  $\rho$ , so all representations in an *L*-packet  $\Pi(\varphi)$  (see §4.5) have the same formal degree.

# 6. Generic representations

In this section we determine the generic representations in our *L*-packets  $\Pi(\varphi)$ . Only quasi-split groups have generic representations, so these can only occur in packets  $\Pi(\varphi, \omega)$  for  $\omega$  belonging to the kernel of the map  $j_G : H^1(\mathbf{F}, G) \to H^1(\mathbf{F}, G_{\mathrm{ad}})$  induced by the adjoint map  $j: G \to G_{\mathrm{ad}}$ .

Let **B** be a Borel subgroup of **G** defined over k, and let **U** be the unipotent radical of **B**. We may and shall assume that **B** contains our fixed maximal torus **T**, which is the centralizer of a maximal k-split torus **S**.

A character  $\psi : U^{\mathrm{F}} \longrightarrow \mathbb{C}^{\times}$  is generic if  $\psi$  is nontrivial on each simple root group of  $S^{\mathrm{F}}$  in  $U^{\mathrm{F}}$ . A representation  $\pi \in \mathrm{Irr}(G^{\mathrm{F}})$  is generic if  $\mathrm{Hom}_{U^{\mathrm{F}}}(\pi, \psi) \neq 0$ , for some generic character  $\psi$  of  $U^{\mathrm{F}}$ . We say that  $\pi$  is  $\psi$ -generic if we want to specify  $\psi$ .

If  $\omega \in \ker j_G$  and  $\rho \in \operatorname{Irr}(C_{\varphi}, \omega)$ , the class  $\pi(\varphi, \rho) \in \Pi(\varphi, \omega)$  is generic if some (equivalently, every) representation in  $\pi(\varphi, \rho)$  is generic.

Generic characters and representations for finite reductive groups are defined similarly.

6.1. Depth-zero generic characters and representations. The first section of this chapter concerns all generic depth-zero supercuspidal representations, not just those arising in our *L*-packets.

Given a hyperspecial vertex  $x \in \mathcal{A}_{ad}^{\vartheta}$ , set  $U_x := U \cap G_x$ ,  $U_x^+ := U \cap G_x^+$ . The quotient  $U_x := U_x/U_x^+$  is the unipotent radical of an F-stable Borel subgroup of  $G_x$ . We say that a character  $\psi : U^F \longrightarrow \mathbb{C}^{\times}$  has *depth-zero at x* if the restriction of  $\psi$  to  $U_x^F$  factors through a generic character  $\psi_x$  of  $U_x^F$ . Note that a depth-zero character at x is automatically generic for  $U^F$ , since x is hyperspecial. Moreover, any generic character  $\psi_x$  of  $U_x^F$  arises from some  $\psi$ having depth-zero at x (using, for example, [27, 24.12]).

Let  $\kappa^{\circ} \in \operatorname{Irr}(G_x^{\mathrm{F}})$  be the inflation of an irreducible cuspidal representation of  $\mathsf{G}_x^{\mathrm{F}}$ , and let  $\kappa$  be an extension of  $\kappa^{\circ}$  to  $Z^{\mathrm{F}}G_x^{\mathrm{F}}$ . In this chapter, it is convenient to use the notation

(24) 
$$\pi(x,\kappa) := \operatorname{ind}_{Z^{\mathsf{F}}G^{\mathsf{F}}}^{G^{\mathsf{F}}} \kappa$$

for the compactly induced representation of  $G^{\rm F}$ . Since x is hyperspecial, the normalizer of  $G_x^{\rm F}$  in  $G^{\rm F}$  is  $Z^{\rm F}G_x^{\rm F}$ , so that [44, 6.6] implies that  $\pi(x,\kappa)$  is an irreducible depth-zero supercuspidal representation of  $G^{\rm F}$ .

LEMMA 6.1.1. Let  $x \in \mathcal{A}_{ad}^{\vartheta}$  be a hyperspecial vertex, let  $\psi$  be a character of  $U^{\mathrm{F}}$  having depth-zero at x, and let  $\psi_x$  be the corresponding generic character of  $U_x^{\mathrm{F}}$  as above. Assume that  $\kappa^{\circ}$  is  $\psi_x$ -generic. Then  $\pi(x, \kappa)$  is  $\psi$ -generic.

*Proof.* This follows from Frobenius reciprocity: Let  $V \subset \pi(x, \kappa)$  be the space of functions supported on  $Z^{\mathrm{F}}G_x^{\mathrm{F}}U^{\mathrm{F}}$ . Then  $V \simeq \operatorname{ind}_{U^{\mathrm{F}}}^{U^{\mathrm{F}}} \kappa$  as representa-

tions of  $U^{\rm F}$ , and V is a  $U^{\rm F}$ -stable direct summand of  $\pi(x, \kappa)$ . We have

$$0 \neq \operatorname{Hom}_{U_x^{\mathrm{F}}}(\kappa, \psi_x) = \operatorname{Hom}_{U^{\mathrm{F}}}(\operatorname{ind}_{U_x^{\mathrm{F}}}^{U^{\mathrm{F}}} \kappa, \psi)$$
$$= \operatorname{Hom}_{U^{\mathrm{F}}}(V, \psi)$$
$$\subset \operatorname{Hom}_{U^{\mathrm{F}}}(\pi(x, \kappa), \psi).$$

The next result shows that all generic depth-zero supercuspidals are of the form  $\pi(x, \kappa)$  as constructed in (24) above.

LEMMA 6.1.2. Let  $\psi$  be a generic character of  $U^{\mathrm{F}}$ , and let  $\pi$  be an irreducible supercuspidal depth-zero  $\psi$ -generic representation of  $G^{\mathrm{F}}$ . Then there is a hyperspecial vertex  $x \in \mathcal{A}^{\vartheta}_{\mathrm{ad}}$  and a cuspidal representation  $\kappa^{\circ}$  of  $\mathbf{G}^{\mathrm{F}}_{x}$  (which we inflate to a representation of  $G^{\mathrm{F}}_{x}$ ), such that the following hold.

- (1)  $\psi$  has depth-zero at x, and  $\kappa^{\circ}$  is a  $\psi_x$ -generic representation of  $G_x^{\rm F}$ .
- (2) There is an extension of  $\kappa^{\circ}$  to a representation  $\kappa$  of  $Z^{\mathrm{F}}G_x^{\mathrm{F}}$ , such that  $\pi \simeq \pi(x, \kappa)$ .

*Proof.* From [44, 6.8] there is a vertex  $z \in \mathcal{A}_{ad}^{\vartheta}$ , a cuspidal representation  $\kappa_z$  of  $\mathsf{G}_z^{\mathrm{F}}$ , and a representation  $\dot{\kappa}_z$  of the normalizer  $\dot{G}_z^{\mathrm{F}}$  of  $G_z^{\mathrm{F}}$  in  $G^{\mathrm{F}}$  such that  $\kappa_z$  appears in  $\dot{\kappa}_z|_{G_z^{\mathrm{F}}}$  and  $\pi \simeq \operatorname{ind}_{\dot{G}_z^{\mathrm{F}}}^{G^{\mathrm{F}}} \dot{\kappa}_z$ .

We may assume that z is contained in the closure of our fixed alcove  $jC^{\vartheta} \subset \mathcal{A}_{ad}^{\vartheta}$ . Let  $\tilde{\Phi}$  be the set of affine roots of **S** in **G**. For any point y in the closure of  $jC^{\vartheta}$ , we set

$$\tilde{\Phi}_y := \{ \tilde{\alpha} \in \Phi : \ \tilde{\alpha}(y) = 0 \}, 
\tilde{\Phi}_y^+ := \{ \tilde{\alpha} \in \Phi_y : \ \tilde{\alpha}|_C > 0 \}.$$

Then  $\tilde{\Phi}_y$  is a spherical root system, and  $\tilde{\Phi}_y^+$  is a set of positive roots in  $\tilde{\Phi}_y$ . We let  $\tilde{\Pi}_y$  be the unique base of  $\tilde{\Phi}_y$  contained in  $\tilde{\Phi}_y^+$ .

Let  $\Phi_y$ ,  $\Phi_y^+$ ,  $\Pi_y$  be the respective sets of gradients of the affine roots in  $\tilde{\Phi}_y$ ,  $\tilde{\Phi}_y^+$ ,  $\tilde{\Pi}_y$ . Each of these sets lies in  $\Phi_o$ , a set upon which  $W_o^\vartheta$  acts. The roots in  $\Pi_y$  are nondivisible in  $\Phi_y$ , and form a base of the reduced root system consisting of nondivisible roots in  $\Phi_y$ .

Let

$$_{z}W_{o}^{\vartheta}:=\{w\in W_{o}^{\vartheta}:\ w^{-1}\Pi_{z}\subset \Phi_{o}^{+}\}.$$

Since  $\pi$  is  $\psi$ -generic and is a quotient of  $\operatorname{ind}_{G_z}^{G^F} \kappa_z$ , we have

$$\operatorname{Hom}_{G^{\mathrm{F}}}(\operatorname{ind}_{G_{z}^{\mathrm{F}}}^{G^{\mathrm{F}}}\kappa_{z},\operatorname{Ind}_{U^{\mathrm{F}}}^{G^{\mathrm{F}}}\psi)\neq 0.$$

As in the proof of [47, Lemma 4], this implies that there exists  $n \in N^{\mathrm{F}}$  whose image  $v \in W_o^{\vartheta}$  belongs to  $_z W_o^{\vartheta}$  and such that  $n_* \psi|_{G_z^+ \cap^n U^{\mathrm{F}}}$  is trivial, while  $n_* \psi|_{G_z \cap^n U^{\mathrm{F}}}$  appears in  $\kappa_z|_{G_z \cap^n U^{\mathrm{F}}}$ . By [47, Lemma 2], the image  $V_z^F$  of  $G_z \cap {}^n U^F$  in  $G_z^F$  is the maximal unipotent subgroup of  $G_z^F$  generated by root groups  $U_\beta^F$  for  $\beta \in \Pi_z$ . Let  $\theta$  be the character of  $V_z^F$  obtained from the restriction of  ${}^n \psi$  to  $G_z \cap {}^n U^F$ . We have seen that  $\theta$  appears in  $\kappa_z|_{V_z^F}$ .

We claim that  $v^{-1}\Pi_z \subset \Pi_o$ . Suppose not, and choose  $\beta \in \Pi_z$  such that  $v^{-1}\beta \in \Phi_o^+ \setminus \Pi_o$ . Then the root group  $U_{v^{-1}\beta}^{\rm F}$  is contained in the kernel of  $\psi$ , so that  $\theta$  is trivial on the simple root group  $\mathsf{U}_{\beta}^{\rm F}$  in  $\mathsf{V}_z^{\rm F}$ . This contradicts the cuspidality of  $\kappa_z$ . So  $v^{-1}\Pi_z \subset \Pi_o$ ; hence in fact  $v^{-1}\Pi_z = \Pi_o$ , since  $|\Pi_z| = |\Pi_o| = \dim \mathcal{A}_{\rm ad}^{\vartheta}$ .

We have shown, moreover, that for each  $\alpha \in \Pi_o$ , the character  ${}^n\psi$  is trivial on  $G_z^+ \cap U_{v\alpha}^{\mathrm{F}}$ , and nontrivial on  $G_z \cap U_{v\alpha}^{\mathrm{F}}$ . Hence  $\psi$  is trivial on  $G_{n^{-1}\cdot z}^+ \cap U_{\alpha}^{\mathrm{F}}$ and nontrivial on  $G_{n^{-1}\cdot z} \cap U_{\alpha}^{\mathrm{F}}$ .

It now suffices to prove that the vertex z is hyperspecial. For then the previous paragraph shows that  $\psi$  has depth-zero at  $x := n^{-1} \cdot z$ , and taking  $\kappa^{\circ} := \operatorname{Ad}(n^{-1})_* \kappa_z$ ,  $\kappa = \operatorname{Ad}(n^{-1})_* \dot{\kappa}_z$  will satisfy the conclusions of the lemma.

Since  $v\Pi_o = \Pi_z$ , it is clear that z is special, but not immediately clear that it is hyperspecial. Let  $\alpha \in \Pi_o$ . Since  $v\alpha \in \Pi_z$ , there is  $k_\alpha \in \mathbb{Z}$  such that  $v\alpha - k_\alpha \in \tilde{\Pi}_z$ . It follows that

$$z = \prod_{\alpha \in \Pi_o} t_{k_\alpha v \lambda_\alpha} \cdot o,$$

where  $\{\lambda_{\alpha} : \alpha \in \Pi_o\} \subset X_{ad}$  is the dual basis of  $\Pi_o$ . Hence  $z = t \cdot o$ , for an element  $t \in T_{ad}^{F}$ . Since Ad(t) is a k-rational automorphism of  $G^{F}$ , it follows that z is hyperspecial.

6.2. Generic representations in our L-packets. Fix a TRSELP  $\varphi$  with corresponding  $w \in W_o$ . We identify

$$\operatorname{Irr}(C_{\varphi}) = H^{1}(\mathbf{F}_{w}, T) = [X/(1 - w\vartheta)X]_{\operatorname{tor}}.$$

We likewise identify

$$H^{1}(\mathbf{F}_{w}, T_{\mathrm{ad}}) = X_{\mathrm{ad}}/(1 - w\vartheta)X_{\mathrm{ad}}$$

(Note that the latter group is finite.) For  $\lambda \in X_w$ , let  $\rho_{\lambda}$  denote the image of  $\lambda$  in  $H^1(\mathbf{F}_w, T)$ , and  $\rho_{j\lambda}$  the image of  $j\lambda$  in  $H^1(\mathbf{F}_w, T_{ad})$ . Then  $\rho_{j\lambda} = j_w(\rho_{\lambda})$ , where

$$j_w: H^1(\mathbf{F}_w, T) \longrightarrow H^1(\mathbf{F}_w, T_{\mathrm{ad}})$$

is the map induced by the map  $j: G \longrightarrow G_{ad}$ . Recall that  $x_{\lambda}$  is the unique fixed-point of  $t_{\lambda}w\vartheta$  in  $\mathcal{A}_{ad}$ .

LEMMA 6.2.1. For  $\lambda \in X_w$ , the following are equivalent.

(1)  $\rho_{j\lambda} = 1;$ 

841

- (2) the vertex  $x_{\lambda}$  is hyperspecial;
- (3) the representation  $\pi_{\lambda}$  of Section 4.5 is generic.

*Proof.* The representations  $\kappa_{\lambda}$  are generic, by [21, 3.10]. The equivalence of (2) and (3) now follows from Lemmas 6.1.1 and 6.1.2.

To prove the equivalence of (1) and (2), recall that  $x_{\lambda}$  is defined by the relation

$$(1 - w\vartheta)x_{\lambda} = t_{j\lambda} \cdot o.$$

Now  $x_{\lambda}$  is hyperspecial if and only if  $x_{\lambda} \in X_{ad} \cdot o$ , if and only if  $j\lambda \in (1-w\vartheta)X_{ad}$ , if and only if  $\rho_{j\lambda} = 1$ .

For  $\omega \in \ker j_G$ , we set

$$\operatorname{Irr}(C_{\varphi},\omega)_{gen} := \{ \rho \in \operatorname{Irr}(C_{\varphi},\omega) : \pi(\varphi,\rho) \text{ is generic} \}.$$

LEMMA 6.2.2. For  $\omega \in \ker j_G$ ,

$$|\operatorname{Irr}(C_{\varphi},\omega)_{gen}| = [X_{\mathrm{ad}}^{\vartheta}:j(X^{\vartheta})]$$

In particular, the number of generic representations in  $\Pi(\varphi, \omega)$  is independent of the TRSELP  $\varphi$  and the class  $\omega \in \ker j_G$ .

*Proof.* We give the proof assuming that  $p \nmid [X_{ad} : jX]$ . The argument for general p is more complicated (see [19]). In this proof only, we change notation and let  $\mathbf{Z}$  denote the full center of  $\mathbf{G}$ , and set  $Z = G \cap \mathbf{Z}$ . We have a diagram of group homomorphisms

$$\begin{array}{cccc} H^{1}(k, \mathbf{Z}) \xrightarrow{\iota} & H^{1}(\mathbf{F}, G) & \xrightarrow{j_{G}} H^{1}(\mathbf{F}, G_{\mathrm{ad}}) \\ & & & \\ & & & \\ H^{1}(k, \mathbf{Z}) \xrightarrow{\iota_{w}} & H^{1}(\mathbf{F}_{w}, T) & \xrightarrow{j_{w}} H^{1}(\mathbf{F}_{w}, T_{\mathrm{ad}}) \\ & & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & &$$

induced by the inclusions  $\mathbf{Z} \hookrightarrow \mathbf{T} \hookrightarrow \mathbf{G}$ , the adjoint map  $j: G \longrightarrow G_{ad}$ , and  $\operatorname{Ad}(p_0): T \longrightarrow G$ , where  $p_0^{-1} \operatorname{F}(p_0) = \dot{w}$  (see §2.7). The rows are exact at the middle term [51, Prop. 38], and  $\iota = r \circ \iota_w$ . Recall that  $r^{-1}(\omega) = \operatorname{Irr}(C_{\varphi}, \omega)$ . We prove the result by computing  $|\ker \iota|$  in two ways.

We have ker  $\iota_w \subseteq \ker \iota$ , so the  $\iota$ -fibers are unions of  $\iota_w$ -fibers. From Lemma 6.2.1 it follows that

$$\iota_w(\iota^{-1}(\omega)) = \operatorname{Irr}(C_{\varphi}, \omega)_{gen}.$$

This implies that

$$|\ker \iota| = |\iota^{-1}(\omega)| = |\operatorname{Irr}(C_{\varphi}, \omega)_{gen}| \cdot |\ker \iota_w|.$$

Now

$$\ker \iota_w \simeq T_{\mathrm{ad}}^{\mathrm{F}_w} / j(T^{\mathrm{F}_w}),$$

and we have

$$T_{\mathrm{ad}}^{\mathrm{F}_w} = X_{\mathrm{ad}}^{w\vartheta} \times ({}^0T_{\mathrm{ad}})^{\mathrm{F}_w}, \quad j(T^{\mathrm{F}_w}) = j(X^{w\vartheta}) \times j({}^0T^{\mathrm{F}_w}).$$

Since  $X_{\rm ad}^{w\vartheta} = \{0\}$ , it follows that

(25) 
$$|\ker \iota| = |\operatorname{Irr}(C_{\varphi}, \omega)_{gen}| \cdot |({}^{0}T_{\mathrm{ad}})^{\mathrm{F}_{w}}/j({}^{0}T^{\mathrm{F}_{w}})|.$$

On the other hand, we have

$$|\ker \iota| = |G_{\mathrm{ad}}^{\mathrm{F}}/j(G^{\mathrm{F}})|.$$

Since **G** is quasi-split, [8, 5.6] implies that the inclusion  $T_{ad} \hookrightarrow G_{ad}$  induces a bijection

$$T_{\mathrm{ad}}^{\mathrm{F}}/j(T^{\mathrm{F}}) \xrightarrow{\sim} G_{\mathrm{ad}}^{\mathrm{F}}/j(G^{\mathrm{F}}).$$

Since  $T_{\rm ad}^{\rm F} = X_{\rm ad}^{\vartheta} \times ({}^{0}T_{\rm ad})^{\rm F}$ , we have

$$T_{\mathrm{ad}}^{\mathrm{F}}/j(T^{\mathrm{F}}) = [X_{\mathrm{ad}}^{\vartheta}/j(X^{\vartheta})] \times ({}^{0}T_{\mathrm{ad}})^{\mathrm{F}}/j({}^{0}T^{\mathrm{F}}),$$

so that

(26) 
$$|\ker \iota| = |X_{\mathrm{ad}}^{\vartheta}/j(X^{\vartheta})| \cdot |({}^{0}T_{\mathrm{ad}})^{\mathrm{F}}/j({}^{0}T^{\mathrm{F}})|.$$

Comparing Equations (25) and (26), we see that the proof boils down to showing that

(27) 
$$|({}^{0}T_{\mathrm{ad}})^{\mathrm{F}_{w}}/j({}^{0}T^{\mathrm{F}_{w}})| = |({}^{0}T_{\mathrm{ad}})^{\mathrm{F}}/j({}^{0}T^{\mathrm{F}})|.$$

If  $p \nmid [X_{ad} : jX]$ , then  $jX \otimes R_K^{\times} = X_{ad} \otimes R_K^{\times}$ , and so we have an exact sequence

$$1 \longrightarrow {}^0T \cap Z \longrightarrow {}^0T \stackrel{j}{\longrightarrow} {}^0T_{\mathrm{ad}} \longrightarrow 1.$$

Since  $H^1(\mathbf{F}_w, {}^0T) = H^1(\mathbf{F}, {}^0T) = 1$  and w acts trivially on Z, it follows that both sides of Equation (27) are equal to  $|H^1(\mathbf{F}, {}^0T \cap Z)|$ .

It follows from [60, 2.5] that  $[X_{ad}^{\vartheta}: j(X^{\vartheta})]$  is the number of  $G^{F_u}$ -orbits of hyperspecial vertices in  $\mathcal{B}(G^{F_u})$ . Lemma 6.2.2 leads one to expect that each of these orbits supports a unique generic representation in  $\Pi_u(\varphi)$ . We will prove this in a few steps, as follows.

LEMMA 6.2.3. Let  $F_u$  be a quasi-split Frobenius, and let S be an  $F_u$ -minisotropic torus in G. Assume that the unique fixed-point x of  $S^{F_u}$  in  $\mathcal{B}(G_{ad})^{F_u}$ is hyperspecial. Then

$$N(G^{\mathcal{F}_u}, S)/S^{\mathcal{F}_u} = N(G, S^{\mathcal{F}_u})/S.$$

Proof. Let  $n \in N(G, S^{F_u}) \subset N(G, S)$ . Since x is hyperspecial and is contained in the apartment of S in  $\mathcal{B}(G_{ad})$ , we have  $N(G, S) = N(G_x, S)S$ , and so we may assume  $n \in N(G_x, S^{F_u})$ . Then  $F_u(n) = nt$  for some  $t \in S \cap G_x = {}^0S$ . Choose  $d \ge 1$  such that  $F_u^d(n) = n$ . If d = 1 there is nothing to prove, so assume d > 1. This implies that  $t F_u(t) \cdots F_u^{d-1}(t) = 1$ . By Lemma 2.3.1 there is  $s \in {}^0T$  such that  $t = s F_u(s)^{-1}$ , so that  $F_u(ns) = ns$ .

Returning to the notation of Section 4.6, let  $u \in \omega \in \ker j_G$ , and suppose  $\lambda, \mu \in r^{-1}(\omega)$  are such that  $\rho_{\lambda}, \rho_{\mu} \in \ker j_w$ . It follows from Lemma 6.2.1 that  $v_{\lambda} := m_{\lambda} \cdot x_{\lambda}$  and  $v_{\mu} := m_{\mu} \cdot x_{\mu}$  are hyperspecial vertices in  $\mathcal{A}_{\mathrm{ad}}^{\mathrm{F}_u}$ . The representations  $\pi_u(\varphi, \rho_{\lambda})$  and  $\pi_u(\varphi, \rho_{\mu})$  are induced from the stabilizers in  $G^{\mathrm{F}_u}$  of  $v_{\lambda}$  and  $v_{\mu}$ , respectively.

LEMMA 6.2.4. Assume that  $v_{\lambda}$  and  $v_{\mu}$  are  $G^{F_u}$ -conjugate hyperspecial vertices. Then  $\rho_{\lambda} = \rho_{\mu}$ .

*Proof.* We first prove that  $S_{\lambda}$  and  $S_{\mu}$  are  $G^{F_u}$ -conjugate. Since  $G^{F_u} = G_{v_{\lambda}}^{F_u} N^{F_u} G_{v_u}^{F_u}$ , there is  $n \in N^{F_u}$  such that  $n \cdot v_{\mu} = v_{\lambda}$ . The  $F_u$ -minisotropic tori

$$S_1 := S_\lambda, \qquad S_2 := {}^n S_\mu$$

both have  $v_{\lambda}$  as their unique fixed-point in  $\mathcal{B}(G_{\mathrm{ad}})^{\mathrm{F}_{u}}$ . Let  $\mathsf{T}$  and  $\mathsf{S}_{i}$  be the images of  $T \cap G_{v_{\lambda}}$  and  $S_{i} \cap G_{v_{\lambda}}$ , respectively, in  $\mathsf{G}_{v_{\lambda}}$ .

 $\operatorname{Set}$ 

$$k_1 := q_\lambda m_\lambda^{-1}, \qquad k_2 := n q_\mu m_\mu^{-1} n^{-1}$$

Then  $k_i \in G_{v_\lambda}$  and  $S_i = \operatorname{Ad}(k_i)T$  for i = 1, 2. Let  $\bar{k}_i$  be the image of  $k_i$  in  $\mathsf{G}_{v_\lambda}$ , so that  $\mathsf{S}_i = \operatorname{Ad}(\bar{k}_i)\mathsf{T}$ .

Using Equation (10) we find that

$$k_1^{-1} \operatorname{F}_u(k_1) \equiv m_{\lambda} \cdot w u^{-1} \cdot \operatorname{F}_u(m_{\lambda})^{-1} \mod T,$$
  
$$k_2^{-1} \operatorname{F}_u(k_2) \equiv n m_{\mu} \cdot w u^{-1} \cdot \operatorname{F}_u(n m_{\mu})^{-1} \mod T.$$

Since  $v_{\lambda}$  is hyperspecial, every class in N/T has a representative in  $N \cap G_{v_{\lambda}}$ . Applying this to  $m_{\lambda}T$ ,  $nm_{\mu}T$  and  $wu^{-1}T$ , we obtain that  $\bar{k}_{1}^{-1} F_{u}(\bar{k}_{1})$  and  $\bar{k}_{2}^{-1} F_{u}(\bar{k}_{2})$  are  $F_{u}$ -conjugate in the Weyl group of T in  $G_{v_{\lambda}}$ . This means (cf. [12, 3.3.3]) that  $S_{1}$  and  $S_{2}$  are  $G_{v_{\lambda}}^{F_{u}}$ -conjugate. The uniqueness part of Lemma 8.0.10 then implies that  $S_{1}$  and  $S_{2}$  are  $G^{F_{u}}$ -conjugate. Hence  $S_{\lambda}$  and  $S_{\mu}$  are  $G^{F_{u}}$ -conjugate, as claimed.

By Lemma 2.11.1 there is  $z_o \in W_o^{w\vartheta}$  such that

$$\lambda \equiv z_o \mu \mod (1 - w\vartheta)X.$$

But Lemmas 6.2.3 and 2.11.2 imply that

$$W_o^{w\vartheta} = W_{o,\mu}^{w\vartheta}$$

Hence  $\lambda \equiv \mu \mod (1 - w\vartheta)X$ , so  $\rho_{\lambda} = \rho_{\mu}$ .

Remark 6.2.5. Lemma 6.2.3 and the last step in the above proof can be seen in another way, as follows. Since  $v_{\lambda}$  is hyperspecial, Lemma 6.2.2 implies that  $\rho_{\lambda} \in \ker j_w = \operatorname{im} i_w : [H^1(k, \mathbb{Z}) \to H^1(\mathbb{F}_w, T)]$ . Since  $W_o^{w\vartheta}$  acts trivially on  $H^1(k, \mathbb{Z})$ , it follows that  $\rho_{\lambda}$  is a  $W_o^{w\vartheta}$ -fixed point in  $H^1(\mathbb{F}_w, T)$ .

Combining Lemmas 6.2.2 and 6.2.4 yields the promised result:

COROLLARY 6.2.6. There is a bijection between the set of generic representations in  $\Pi_u(\varphi)$  and the set of  $G^{F_u}$ -orbits of hyperspecial vertices in  $\mathcal{B}(G_{ad})^{F_u}$ , such that a generic representation is induced from the stabilizer of any hyperspecial vertex in the corresponding orbit.

Remark 6.2.7. If **G** has connected center, then  $G_x$  has connected center for any hyperspecial vertex  $x \in \mathcal{B}(G)$ . Assume x is  $F_u$ -stable. It follows from Proposition 5.26 and Theorems 6.8 and 10.7 of [20] that every cuspidal generic representation of  $G_x$  is of the form  $\pm R_{S,\theta}^{G_x}$  for some  $F_u$ -minisotropic maximal torus  $S \subset G_x$  and  $\theta \in \operatorname{Irr}(S^{F_u})$  in general position. By Lemma 6.1.2, this implies that every depth-zero generic supercuspidal representation of  $G^{F_u}$  appears in  $\Pi_u(\varphi)$  for some TRSELP  $\varphi$ .

### 7. Topological Jordan decomposition

We define the set of *compact elements* in G by

$$G_0 := \bigcup_{x \in \mathcal{B}(G)} G_x,$$

and the set of topologically unipotent elements in G by

$$G_{0^+} = \bigcup_{x \in \mathcal{B}(G)} G_x^+$$

We define  $\mathfrak{g}_0$  and  $\mathfrak{g}_{0^+}$  similarly. These  $G \rtimes \langle F \rangle$ -stable subsets of G will play an important role in this paper.

Remark 7.0.8. From [16] we have that if  $x \in \mathcal{B}(G)$ , then

$$G_0 \cap \operatorname{stab}_G(x) = G_x.$$

Let p denote the characteristic of  $\mathfrak{f}$ . Choose m such that for all F-stable facets J in  $\mathcal{B}(G)$  and all elements  $g \in \mathsf{G}_J^F$  we have  $g^{(p^m)} = \mathfrak{s}$  where  $\mathfrak{s}$  denotes the semisimple component in the Jordan decomposition of g.

Suppose  $\gamma \in G_0^F$ . Let  $J \subset \mathcal{B}(G)$  be any *F*-stable facet such that  $\gamma \in G_J$ . Since  $\gamma \in G_J^F$ , it follows that we can define

$$\gamma_{\rm s} := \lim_{n \to \infty} \gamma^{(p^{mn})}.$$

This limit does not depend on m, and the element  $\gamma_s$  has finite order prime to p. We set

$$\gamma_{\rm u} = \gamma \cdot \gamma_{\rm s}^{-1}.$$

The topological Jordan decomposition is the commuting factorization

$$\gamma = \gamma_{\rm s} \gamma_{\rm u} = \gamma_{\rm u} \gamma_{\rm s}$$

We have  $\gamma_{s}$ ,  $\gamma_{u} \in G_{J}^{F}$ . Moreover,  $\gamma_{s}$  is semisimple and has semisimple image in  $G_{J}$  while  $\gamma_{u}$  has unipotent image in  $G_{J}$ . In particular,  $\gamma_{u}$  is topologically unipotent. We say that  $\gamma$  is topologically semisimple if  $\gamma = \gamma_{s}$ , that is, if  $\gamma = \gamma^{p^{m}}$ .

The topological Jordan decomposition  $\gamma = \gamma_{\rm s} \gamma_{\rm u}$  is the unique commuting factorization of  $\gamma$  as a product of a topologically semisimple element and a topologically unipotent element. This implies that if  $g \in \mathbf{G}$  is chosen so that  ${}^{g}\gamma \in G^{F}$ , then  ${}^{g}(\gamma_{\rm s}) = ({}^{g}\gamma)_{\rm s}$  and  ${}^{g}(\gamma_{\rm u}) = ({}^{g}\gamma)_{\rm u}$ .

LEMMA 7.0.9. Suppose  $\gamma \in G_0^F$  has topological Jordan decomposition  $\gamma = \gamma_s \gamma_u$ . Then  $\gamma$ ,  $\gamma_s$ , and  $\gamma_u$  all belong to  $G_{\gamma_s}$ . Moreover, if  $\gamma \in G^{rss}$ , then  $\gamma_u \in G^{rss}_{\gamma_s}$ .

*Proof.* Choose a Borel subgroup  $\mathbf{B} < \mathbf{G}$  containing  $\gamma$ . Since  $\mathbf{B} \cap G$  is a closed subgroup of G, both  $\gamma_{\rm s}$  and  $\gamma_{\rm u}$  belong to  $\mathbf{B} \cap G$ . Since  $\gamma_{\rm s}$  is semisimple, it follows from [6, Th. 10.6 (5ii)] that the centralizer in  $\mathbf{B}$  of  $\gamma_{\rm s}$  is connected. Thus,  $\gamma$ ,  $\gamma_{\rm s}$ , and  $\gamma_{\rm u}$  belong to  $\mathbf{B}_{\gamma_{\rm s}} \cap G \subset G_{\gamma_{\rm s}}$ .

The centralizer of  $\gamma_u$  in  $G_{\gamma_s}$  has finite index in the centralizer of  $\gamma$  in G. This implies the last assertion.

Since  $\gamma_s$  is compact and has finite order prime to p, the results of [46] combined with Remark 7.0.8 allow us to identify

(28) 
$$\mathcal{B}(G_{\gamma_{\mathrm{s}}}) = \mathcal{B}(G)^{\gamma_{\mathrm{s}}}.$$

More precisely, there is an unramified maximal torus S of G containing  $\gamma_s$ , and a bijection from the apartment of S in  $\mathcal{B}(G_{\gamma_s})$  to the apartment of S in  $\mathcal{B}(G)$ which extends to a  $G_{\gamma_s}$ -equivariant bijection  $\mathcal{B}(G_{\gamma_s}) \xrightarrow{\sim} \mathcal{B}(G)^{\gamma_s}$ . In particular,  $\mathbf{G}_{\gamma_s}$  and  $\mathbf{G}$  have the same K-rank.

For an exhaustive treatment of the topological Jordan decomposition, see [52].

### 8. Unramified and minisotropic maximal tori

Recall that we are assuming **G** is K-split, and that we say a subgroup S < G is a maximal unramified torus in G if  $S = \mathbf{S}(K)$ , where **S** is a K-split maximal torus in **G** such that **S** is defined over k.

All maximal unramified tori in G can be found as follows.

LEMMA 8.0.10. Suppose we are given a nonempty F-stable subset J of a facet in  $\mathcal{B}(G)$  or  $\mathcal{B}(G_{ad})$  and an F-stable maximal torus  $S < G_J$ . Then there exists a maximal unramified torus S in G such that

(1)  $J \subset \mathcal{A}(S);$ 

(2) the image of  $S \cap G_J$  in  $G_J$  is exactly S.

Moreover, S is unique up to conjugacy by  $G_J^{+F}$ .

*Proof.* The existence of S is shown in the proof of [10, 5.1.10]. The uniqueness is proved in [14, Lemma 2.2.2].

Such an S is called a *lift* of (J, S).

A maximal unramified torus S in G is called *F*-minisotropic in G if  $X_*(\mathbf{S})^F = X_*(\mathbf{Z})$ , where **Z** is the identity component of the maximal k-split torus in the center of **G**.

Likewise, a maximal f-torus S in a reductive f-group G with Frobenius F is called F-minisotropic in G if  $X_*(S)^F = X_*(Z)$ , where Z is the maximal f-split torus in the center of G.

Let  $\mathfrak{T}(G)$  be the set of *F*-minisotropic maximal tori in *G*. If  $S \in \mathfrak{T}(G)$ , then there exists a unique *F*-stable facet  $J \subset \mathcal{B}(G)$  such that

$$\mathcal{A}(S)^F = J^F$$

The unique parahoric subgroup  ${}^{0}S$  of S is given by

$$^{0}S = S \cap G_{J}$$

Note that  $N(G,S)^F$  preserves  $\mathcal{A}(S)^F$ , hence normalizes  $G_J^F$  and  $G_J^{+F}$ . In particular,  $G_J^{+F}N(G,S)^F$  is a subgroup of  $G^F$ .

Let S be the image of  $S \cap G_J$  in  $G_J$ . Then S is an F-minisotropic torus in  $G_J$ , and S is a lift of (J, S).

Fix now  $S \in \mathfrak{T}(G)$  and a topologically semisimple element  $\gamma \in G_0^F$ . For our later integral calculations we must consider the two sets

$$E(\gamma, S) := \{ g \in G^F : {}^g \gamma \in G_J, \quad \overline{g\gamma} \in \mathsf{S} \}, \\ \tilde{D}(\gamma, S) := \{ d \in G^F : {}^d \gamma \in S \}.$$

In other terms,  $\tilde{D}(\gamma, S)$  is the set of elements of  $G^F$  which conjugate S into  $G_{\gamma}$ , and  $E(\gamma, S)$  is the set of elements of  $G^F$  which send some  $G_J^{+F}$ -conjugate of S into  $G_{\gamma}$  and whose inverse sends J into  $\mathcal{B}(G_{\gamma})$ . Since  $\gamma \in G_0^F$ , we have  $\tilde{D}(\gamma, S) \subset E(\gamma, S)$ .

Now, there are obvious actions, by multiplication, of  $G_J^{+F}N(G,S)^F \times G_{\gamma}^F$ on  $E(\gamma, S)$ , and of  $N(G,S)^F \times G_{\gamma}^F$  on  $\tilde{D}(\gamma, S)$ .

LEMMA 8.0.11. The inclusion  $\tilde{D}(\gamma, S) \hookrightarrow E(\gamma, S)$  induces a bijection  $N(G, S)^F \setminus \tilde{D}(\gamma, S) / G_{\gamma}^F \xrightarrow{\sim} G_J^{+F} N(G, S)^F \setminus E(\gamma, S) / G_{\gamma}^F.$ 

Both sets of double cosets are finite.

Proof. The set  $N(G, S)^F \setminus \tilde{D}(\gamma, S)/G_{\gamma}^F$  parametrizes  $G_{\gamma}^F$ -conjugacy classes of F-minisotropic tori in  $G_{\gamma}$  which lie in the  $G^F$ -conjugacy class of S. Since  $G_{\gamma}^F$  has only finitely many conjugacy classes of unramified maximal tori, the set  $N(G, S)^F \setminus \tilde{D}(\gamma, S)/G_{\gamma}^F$  is finite.

We now prove injectivity. Suppose we have  $d, d' \in \tilde{D}(\gamma, S)$ , and  $h \in G_J^{+F}$ ,  $n \in N(G, S)^F$ ,  $g \in G_\gamma^F$ , such that d' = nhdg. Replacing d' by  $n^{-1}d'g^{-1}$ , we may assume without loss of generality that d' = hd. This means that  ${}^d\gamma$  and  ${}^{hd}\gamma$  both belong to S, and being compact,  ${}^d\gamma$  and  ${}^{hd}\gamma$  in fact belong to  $S \cap G_J$ . Since  $h \in G_J^{+F}$ , both  ${}^d\gamma$  and  ${}^{hd}\gamma$  have the same image in S. Hence we can write  ${}^{hd}\gamma = {}^d\gamma\gamma_1$ , where  $\gamma_1 \in G_J^{+F} \cap S$  is topologically unipotent. But then  ${}^d\gamma\gamma_1 = \gamma_1{}^d\gamma$ , and since  ${}^{hd}\gamma$  is topologically semisimple, we must have  $\gamma_1 = 1$ , by uniqueness of the topological Jordan decomposition. It follows that S and  ${}^{h-1}Sh$  are two lifts of (S, J) in  ${}^dG_{\gamma_s}$ . By Lemma 8.0.10, there is  $k \in ({}^dG_{\gamma_s})_J^{+F}$  such that  $kSk^{-1} = h^{-1}Sh$ . This implies that  $h \in N(G, S)^F \cdot {}^d(G_{\gamma_s}^F)$ , proving injectivity.

For surjectivity, suppose  $g \in E(\gamma, S)$ , and let  $H = {}^{g}G_{\gamma}$ . Then  ${}^{g}\gamma$  fixes J pointwise, and so by Equation (28), J is contained in a facet in the building  $\mathcal{B}(H)$  of H. We let  $H_{J}$  denote the corresponding parahoric subgroup of H. Then  ${}^{g}\gamma \in H_{J}$ .

Considering root data, we find an f-isomorphism  $\iota : (\mathsf{G}_J)_{\overline{s\gamma}} \xrightarrow{\sim} \mathsf{H}_J$  making the following diagram commutative.

$$\begin{array}{rcccc} H \cap G_J &=& H_J \\ \downarrow & & \downarrow \\ (G_J)_{\overline{g_{\gamma}}} & \stackrel{\iota}{\longrightarrow} & \mathsf{H}_J. \end{array}$$

We have  $S < (G_J)_{\overline{g\gamma}}$  by hypothesis; hence  $\iota S$  is an F-stable maximal torus in  $H_J$ . Choose a lift S' in H of  $(J, \iota S)$ . Then  $S' \cap H_J = S' \cap G_J$  and so S' is a lift of (J, S) in G. But S is also a lift of (J, S) in G, so that by 8.0.10 there is  $k \in G_J^{+F}$  such that  ${}^kS' = S$ . Since  ${}^g\gamma \in S'$ , we have  ${}^{kg}\gamma \in S$ . This means  $kg \in \tilde{D}(\gamma, S)$ , proving surjectivity.

# 9. Some character computations

In this chapter we give an integral formula for the characters of the representations constructed in Section 4.4. In fact, we define a set of integrals on  $G^F$  which include these characters as a subset. Our eventual goal is to express these integrals as combinations of similar integrals on the set of topologically unipotent elements, in the same way that a Deligne-Lusztig character is expressed as a combination of Green functions.

9.1. Harish-Chandra's character formula. Recall that Z denotes the group of K-rational points of the maximal k-split torus in the center of  $\mathbf{G}$ .

Suppose that Q is an open subgroup of  $G^F$  containing  $Z^F$  such that Q is compact modulo  $Z^F$ . Suppose also that  $\kappa$  is a representation of Q for which the compactly-induced representation  $\pi := \operatorname{ind}_Q^{G^F} \kappa$  of  $G^F$  is irreducible. Let  $\dot{\chi}_{\kappa}$  denote the extension by zero of the character of  $\kappa$  to a function on  $G^F$ . In [26] Harish-Chandra showed that the value of the character of  $\pi$  at  $\gamma \in (G^{\operatorname{rss}})^F$ is given by the formula

$$\frac{\operatorname{Deg}(\pi)}{\chi_{\kappa}(1)} \int_{G^{F}/Z^{F}} dg^{*} \int_{L} \dot{\chi}_{\kappa}({}^{gl}\gamma) dl$$

Here  $dg^*$  denotes the quotient measure on  $G^F/Z^F$  with respect to Haar measures dg and dz on  $G^F$  and  $Z^F$ , respectively,  $\text{Deg}(\pi)$  denotes the formal degree of  $\pi$  with respect to  $dg^* = dg/dz$  (see §5), and L is an arbitrary compact open subgroup of  $G^F$  with Haar measure dl normalized so that  $\text{meas}_{dl}(L) = 1$ .

9.2. The character integral. Let S be an F-minisotropic maximal torus in G, and let J be the unique minimal F-stable facet in  $\mathcal{B}(G)$  such that  $\mathcal{A}(S)^F = J^F$ . Recall that  ${}^0S^F = S^F \cap G_J$ , and  $S \cap G_J$  projects onto an F-minisotropic torus S in  $G_J$ .

Let  $\operatorname{Irr}_0(S^F)$  denote the set of depth-zero characters of  $S^F$ . For  $\theta \in \operatorname{Irr}_0(S^F)$ , the restriction of  $\theta$  to  ${}^0S^F$  factors through  $S^F$ , and thus defines a Deligne-Lusztig virtual character  $R_{\mathsf{S},\theta}^{\mathsf{G}_J}$ . Let  $\dot{R}_{\mathsf{S},\theta}^{\mathsf{G}_J}$  denote the natural inflation of  $R_{\mathsf{S},\theta}^{\mathsf{G}_J}$  to a function on  $G_J^F$ , extended by zero to the rest of  $G^F$ .

Define a function  $R(G, S, \theta)$  on  $(G^{rss})^F$  by the integral

$$R(G, S, \theta)(\gamma) := \frac{\operatorname{meas}_{dz}(Z_J^F)}{\operatorname{meas}_{dg}(G_J^F)} \cdot \int_{G^F/Z^F} dg^* \int_L \dot{R}_{\mathsf{S}, \theta}^{\mathsf{G}_J}({}^{gl}\gamma) \, dl.$$

Here L and the measures  $dg^*$ , dl are as in Section 9.1. (The integral converges; see, for example, Lemma 10.0.7.)

Remark 9.2.1. For  $h \in G^F$ , a change of variables shows that

 $R(G, {}^{h}S, h_{*}\theta) = R(G, S, \theta),$ 

where  $h_*\theta = \theta \circ \operatorname{Ad}(h)^{-1}$ . If  $\mathcal{T}$  is a  $G^F$ -orbit of pairs  $(S, \theta)$  with  $S \in \mathfrak{T}(G)$  and  $\theta \in \operatorname{Irr}_0(S^F)$ , we sometimes write

$$R(G,\mathcal{T}) := R(G,S,\theta),$$

for any  $(S, \theta) \in \mathcal{T}$ .

9.3. Relation to characters. Suppose  $\theta \in \operatorname{Irr}_0(S^F)$  is regular, in the sense that  $\theta$  has trivial stabilizer in  $N(G, S^F)/S$ . There is a unique representation  $\kappa$  of  $Z^F G_I^F$  such that

(1) the restriction to  $G_J^F$  of  $\kappa$  has the character  $\varepsilon(\mathsf{G}_J,\mathsf{S}) \cdot \dot{R}_{\mathsf{S},\theta}^{\mathsf{G}_J}$ , and

(2) the restriction of  $\kappa$  to  $Z^F$  is given by the scalar character  $\theta|_{Z^F}$ , times the identity.

We have seen that the induced representation  $\pi := \operatorname{Ind}_{Z^F G_J^F}^{G^F} \kappa$  is irreducible and supercuspidal.

LEMMA 9.3.1. Let  $\Theta_{\pi}$  be the character of the representation  $\pi$  just defined. Then  $\Theta_{\pi}$  vanishes off the set  $Z^F G_0^F$ . For  $z \in Z^F$  and regular semisimple  $\gamma \in G_0^F$ ,

 $\Theta_{\pi}(z\gamma) = \varepsilon(\mathsf{G}_J,\mathsf{S}) \cdot \theta(z) \cdot R(G,S,\theta)(\gamma).$ 

*Proof.* Harish-Chandra's integral formula (see §9.1) makes the vanishing assertion obvious and gives, for  $z \in Z^F$  and regular semisimple  $\gamma \in G_0^F$ , the formula

$$\Theta_{\pi}(z\gamma) = \theta(z) \cdot \frac{\operatorname{meas}_{dg}(G_J^r)}{\operatorname{meas}_{dz}(Z_J^r)} \cdot \frac{\operatorname{Deg}(\pi)}{\dot{R}_{\mathsf{S},\theta}^{\mathsf{G}_J}(1)} \cdot R(G,S,\theta)(\gamma).$$

Consequently, we need to show that

$$\frac{\operatorname{meas}_{dg}(G_J^F)}{\operatorname{meas}_{dz}(Z_J^F)} \cdot \frac{\operatorname{Deg}(\pi)}{\dot{R}_{\mathsf{S},\theta}^{\mathsf{G}_J}(1)} = \varepsilon(\mathsf{G}_J,\mathsf{S}).$$

But, from Remark 5.3 we have

$$\operatorname{Deg}(\pi) \cdot \operatorname{meas}_{dg^*}(Z^F G_J^F / Z^F) = \dim(\kappa),$$

and the claim follows.

9.4. Stable conjugacy of tori and their characters. We want to produce a sum of character integrals that will be stable. In the situation of Section 9.3, these sums will specialize to the sum of characters over an L-packet, as defined in Section 4.6. Our integral sums are based on the notion of stable conjugacy of unramified tori and their characters.

Recall that  $\mathfrak{T}(G)$  denotes the set of F-minisotropic maximal tori in G. We say that two tori  $S_1, S_2 \in \mathfrak{T}(G)$  are G-stably conjugate if there is  $g \in G$ such that  ${}^g(S_1^F) = S_2^F$ . This defines an equivalence relation on  $\mathfrak{T}(G)$ , whose equivalence classes are called G-stable classes. The set of G-stable classes injects into  $H^1(F, N/T)$  as follows. Any two maximal unramified tori in G are conjugate by an element of G. For  $S \in \mathfrak{T}(G)$ , write  $S = {}^gT$ , for  $g \in G$ . Since F(S) = S, we have an element  $n := g^{-1}F(g) \in Z^1(F, N)$ . Projection to N/Tgives an element  $\bar{n} := g^{-1}F(g)T \in Z^1(F, N/T)$ . One checks that the class  $[\bar{n}]$ of  $\bar{n}$  in  $H^1(F, N/T)$  is independent of g. Note that  $S^F = {}^g(T^{F_n})$ , where, as usual,  $F_n = \operatorname{Ad}(n) \circ F$ .

LEMMA 9.4.1. Suppose 
$$h \in G$$
, and  $n, m \in N$ . Then  
 $h^{-1}mF(h) \in nT \Leftrightarrow {}^{h}(T^{F_n}) = ({}^{h}T)^{F_m}.$ 

*Proof.* Implication  $\Rightarrow$  is straightforward. For the converse, choose a strongly regular element  $t \in T^{F_n}$ . From the equation  $F_m({}^ht) = {}^ht$ , we find that the element  $h^{-1}mF(h)n^{-1}$  centralizes t, hence lies in T.

For  $v = nT \in N/T$ , set  $F_v = F_n$ , and define

 $\mathcal{T}_v := \{ S \in \mathfrak{T}(G) : S^F = {}^g(T^{F_v}) \text{ for some } g \in G \}.$ 

LEMMA 9.4.2. The sets  $T_v$  have the following properties.

- (1) If  $T_v$  is nonempty, then  $T_v$  is a G-stable class in  $\mathfrak{T}(G)$ .
- (2) Every G-stable class in  $\mathfrak{T}(G)$  is of the form  $\mathcal{T}_v$  for some  $v \in N/T$ .
- (3) For  $v, v' \in N/T$ , we have  $\mathcal{T}_v = \mathcal{T}_{v'}$  if and only if [v] = [v'] in  $H^1(F, N/T)$ .
- (4) If **G** is k-quasi-split, then  $\mathcal{T}_v$  is nonempty.

*Proof.* See [14].

For each  $S \in \mathcal{T}_v$ , Lemma 9.4.1 implies that there is  $g \in G$  such that  $S = {}^gT$ and  $g^{-1}F(g) \in v$ . Note that the choice of g is not uniquely determined by S; two choices of g differ by an element of  $N(G, S^F)$ . The map  $\operatorname{Ad}(g) : T \longrightarrow S$ intertwines  $(T, F_v)$  and (S, F). For each depth-zero character  $\chi \in \operatorname{Irr}_0(T^{F_v})$ , we have a corresponding character  $g_*\chi \in \operatorname{Irr}_0(S^F)$ , which depends on the choice of g.

This dependence on g is eliminated by passing to a "covering" of  $\mathcal{T}_v$ , as follows. Consider the set of pairs

$$\hat{\mathfrak{T}}(G) := \{ (S, \theta) : S \in \mathfrak{T}(G) \text{ and } \theta \in \operatorname{Irr}_0(S^F) \}.$$

We say that two pairs  $(S_1, \theta_1)$ ,  $(S_2, \theta_2) \in \hat{\mathfrak{T}}(G)$  are *G*-stably conjugate if there is  $g \in G$  such that

- (1)  ${}^{g}(S_{1}^{F}) = S_{2}^{F}$ , and
- (2)  $g_*\theta_1 = \theta_2$ .

The G-stable classes of pairs  $(S, \theta) \in \hat{\mathfrak{T}}(G)$  are parametrized as follows. Fix  $v \in N/T$ ,  $\chi \in \operatorname{Irr}_0(T^{vF})$ , and define

$$\hat{\mathcal{T}}_{v,\chi} := \{ (S,\theta) \in \hat{\mathfrak{T}}(G) : \text{there exists } g \in G \\ \text{such that } S^F = {}^g(T^{F_v}), \text{ and } \theta = q_*\chi \}.$$

LEMMA 9.4.3. (1) If  $\mathcal{T}_v$  is nonempty, then  $\hat{\mathcal{T}}_{v,\chi}$  is a nonempty *G*-stable class in  $\hat{\mathfrak{T}}(G)$ .

- (2) Every G-stable class in  $\hat{\mathfrak{T}}(G)$  is of the form  $\hat{T}_{v,\chi}$  for some  $v \in N/T$ ,  $\chi \in \operatorname{Irr}_0(T^F)$ .
- (3) For  $v \in N/T$ ,  $\chi, \chi' \in \operatorname{Irr}_0(T^{F_v})$ , we have  $\hat{\mathcal{T}}_{v,\chi} = \hat{\mathcal{T}}_{v,\chi'}$  if and only if there is  $n \in N(G, T^{F_v})$  such that  $n_*\chi = \chi'$ .

*Proof.* This follows easily from Lemma 9.4.2.

Thus, we have a partition

$$\hat{\mathfrak{T}}(G) = \coprod_{\substack{v \in N/T \\ \mathcal{T}_v \neq \varnothing}} \prod_{\chi \in \operatorname{Irr}_0(T^{F_v})/N(G, T^{F_v})} \hat{\mathcal{T}}_{v,\chi}$$

of  $\hat{\mathfrak{T}}(G)$  into nonempty G-stable classes.

Projection onto the first factor is a surjection  $p_1 : \hat{T}_{v,\chi} \longrightarrow \mathcal{T}_v$ . Given  $S \in \mathcal{T}_v$  we can project the fiber  $p_1^{-1}(S)$  onto the second factor. This gives a map

$$p_2: p_1^{-1}(S) \longrightarrow \operatorname{Irr}_0(S^{F'}).$$

We define

$$\theta_S^{\chi} = \sum_{\theta \in p_2 p_1^{-1}(S)} \theta$$

To see the dependence on  $\chi$ , choose g as in the definition of  $\hat{T}_{v,\chi}$  above. Then

$$\theta^{\chi}_S = \sum_{\bar{n} \in N(G, S^F)/S} (ng)_* \chi,$$

and the sum is independent of the choice of g.

The character sums  $\theta_S^{\chi}$  have the following stability property.

LEMMA 9.4.4. Suppose  $S_1, S_2 \in \mathcal{T}_v, \gamma \in S_1^F$ , and  $\chi \in \operatorname{Irr}_0(T^{F_v})$ . Then for any  $h \in G$  such that  ${}^h(S_1^F) = S_2^F$ ,

$$\theta_{S_1}^{\chi}(\gamma) = \theta_{S_2}^{\chi}({}^{h}\gamma)$$

*Proof.* This is immediate from the observation that  $h_*[p_2p_1^{-1}(S_1)] = p_2p_1^{-1}(S_2)$ .

9.5. The stable character integral. Fix a G-stable class  $\hat{\mathcal{T}}_{st} \subset \hat{\mathfrak{T}}(G)$ . The group  $G^F$  acts on  $\hat{\mathfrak{T}}(G)$  via  $g \cdot (S, \theta) = ({}^gS, g_*\theta)$ , and  $\hat{\mathcal{T}}_{st}$  is the union of finitely many  $G^F$ -orbits in  $\hat{\mathfrak{T}}(G)$ . By Remark 9.2.1 the function  $R(G, S, \theta)$  depends only on the  $G^F$ -orbit of  $(S, \theta)$ . We can therefore define a function  $R(G, \hat{\mathcal{T}}_{st})$  on  $(G^{rss})^F$  by

$$R(G, \hat{\mathcal{T}}_{\mathrm{st}}) := \sum_{(S, \theta) \in \hat{\mathcal{T}}_{\mathrm{st}}/G^F} R(G, S, \theta),$$

where  $R(G, S, \theta)$  is as defined in Section 9.2. Our eventual goal is to show that the function  $R(G, \hat{T}_{st})$  is stable. But first, we relate  $R(G, \hat{T}_{st})$  to the sum of characters in an *L*-packet.

9.6. Relation to L-packets. In this section we show that the sum of characters in an L-packet, as defined in Section 4.6, can be expressed, up to

851

a sign, as one of the functions  $R(G, T_{st})$  as defined in Section 9.5. We return to the notation used in Section 4.6 and previously, so that  $F = F_u$ . Set  $v = \dot{w}u^{-1}T \in N/T$ , and let  $\chi \in Irr_0(T^{F_w})$  be regular. Note that  $F_v = F_w$ , and by the proof of Lemma 2.11.2, we may identify

$$N(G, T^{\mathbf{F}_w})/T = W_o^{w\vartheta}.$$

For each  $\lambda \in r^{-1}(\omega)$  we have the pair  $(S_{\lambda}, \theta_{\lambda}) = q_{\lambda} \cdot (T, \chi) \in \tilde{T}_{v,\chi}$ . Recall from Lemma 2.6.1 the commutative diagram

$$[X/(1-w\vartheta)X]_{\text{tor}} \longrightarrow [X/(1-\vartheta)X]_{\text{tor}}$$
$$\simeq \downarrow \qquad \qquad \downarrow \simeq$$
$$H^{1}(\mathbf{F}_{w},T) \xrightarrow{\operatorname{Ad}(p_{0})} H^{1}(F,G)$$

where the vertical maps are bijections. Recall that  $[r^{-1}(\omega)]$  denotes the fiber of the map in the top row, and this fiber carries a natural action of  $W_o^{w\vartheta}$ .

LEMMA 9.6.1. Recall that  $v = \dot{w}u^{-1}T$ , and  $\chi \in \operatorname{Irr}_0(T^{F_w})$  is regular. The mappings  $\lambda \mapsto (S_\lambda, \theta_\lambda), \lambda \mapsto S_\lambda$ , respectively, induce bijections

$$\alpha: [r^{-1}(\omega)] \xrightarrow{\sim} \hat{\mathcal{T}}_{v,\chi}/G^{\mathcal{F}_u}, \qquad \beta: [r^{-1}(\omega)]/W_o^{w\vartheta} \xrightarrow{\sim} \mathcal{T}_v/G^{\mathcal{F}_u},$$

which make the following diagram commute.

$$[r^{-1}(\omega)] \xrightarrow{\alpha} \tilde{\mathcal{T}}_{v,\chi}/G^{\mathrm{F}}$$

$$p \downarrow \qquad \qquad \downarrow \bar{p}_{1}$$

$$[r^{-1}(\omega)]/W_{o}^{w\vartheta} \xrightarrow{\beta} \mathcal{T}_{v}/G^{\mathrm{F}_{u}}$$

Here p is the quotient map and  $\bar{p}_1$  is induced by the projection  $p_1$  onto the first factor.

*Proof.* The map  $\beta$  is well-defined and bijective, by Lemma 2.11.1.

If  $\lambda, \mu \in r^{-1}(\omega)$  are congruent modulo  $(1 - w\vartheta)X$ , then from the proof of Lemma 2.10.1 there exists  $s \in S_{\lambda}$  such that  $q_{\mu}q_{\lambda}^{-1}s \in G^{F_{u}}$ . Since

$$q_{\mu}q_{\lambda}^{-1}s \cdot (S_{\lambda}, \theta_{\lambda}) = (S_{\mu}, \theta_{\mu})$$

this shows that the map  $\alpha$  is well-defined.

The fiber of  $\bar{p}_1$  over the  $G^{\mathbf{F}_u}$ -orbit of  $S_\lambda$  in  $\mathcal{T}_v$  is in evident bijection with  $N(G, S_\lambda^{\mathbf{F}_u})/S_\lambda N(G^{\mathbf{F}_u}, S_\lambda)$ . By Lemma 2.11.2, the latter is in bijection with the fiber of p over the class of  $\lambda$  in  $[r^{-1}(\omega)]/W_o^{w\vartheta}$ .

It therefore suffices to prove that  $\alpha$  is injective. Suppose  $g \in G^{\mathbb{F}_u}$ ,  $\lambda, \mu \in r^{-1}(\omega)$  and  $g \cdot (S_\mu, \theta_\mu) = (S_\lambda, \theta_\lambda)$ . As in the proof of Lemma 2.11.1, the element  $q_\lambda^{-1}gq_\mu$  belongs to  $N(T^{\mathbb{F}_w})$ , and projects to an element  $z_o \in W_o^{w\vartheta}$  such that

 $z_o\mu \equiv \lambda \mod (1 - w\vartheta)X$ . But also  $g_*\theta_\mu = \theta_\lambda$ , which means that  $z_o$  fixes  $\chi$ . Since  $\chi$  is regular, we have  $z_o = 1$ , hence  $\mu \equiv \lambda \mod (1 - w\vartheta)X$ .  $\Box$ 

Recall that for  $\lambda \in r^{-1}(\omega)$ ,  $u \in \omega$ , and a TRSELP  $\varphi$  we defined in Section 4.6 the representation

$$\pi_u(\varphi, \rho_\lambda) = \operatorname{Ad}(m_\lambda)_* \pi_\lambda \in \operatorname{Irr}(G^{\mathbf{F}_u}),$$

where  $m_{\lambda}$  is as in Lemma 2.8.1. This construction involved the character  $\chi = \chi_{\varphi} \in \operatorname{Irr}_0(T^{F_w})$  corresponding to  $\varphi$  as in Section 4.3.

LEMMA 9.6.2. Let  $\mathbf{G}_u$  be the inner twist of  $\mathbf{G}$  given by the cocycle  $u \in \omega$ , and let  $\mathbf{T}_w$  be the twist of  $\mathbf{T}$  determined by w. Then for  $\lambda \in r^{-1}(\omega)$ ,

$$\varepsilon(\mathsf{G}_{\lambda},\mathsf{T}_{\lambda}) = \varepsilon(\mathbf{G}_{u},\mathbf{T}_{w}).$$

Hence, this sign is independent of  $\lambda \in r^{-1}(\omega)$ .

*Proof.* The f-rank of  $G_{\lambda}$  equals the k-rank of  $G_{u_{\lambda}}$ , and  $G_{u_{\lambda}} \simeq G_{u}$  over k. Likewise, we have seen that  $\mathbf{T}_{\lambda} \simeq \mathbf{T}_{w}$  over k.

For  $\lambda \in r^{-1}(\omega)$ , let  $\Theta_{\rho_{\lambda}}$  be the character of  $\pi_u(\varphi, \rho_{\lambda})$ . By construction, the function  $\Theta_{\rho_{\lambda}}$  depends only on the class of  $\lambda$  in  $[r^{-1}(\omega)]$ . We can now prove the desired result of this section.

LEMMA 9.6.3. Let  $v = wu^{-1}$  and let  $\chi = \chi_{\varphi}$  be as in Section 4.3. Then

$$\sum_{\lambda \in [r^{-1}(\omega)]} \Theta_{\rho_{\lambda}} = \varepsilon(\mathbf{G}_u, \mathbf{T}_w) \cdot R(G, \hat{\mathcal{T}}_{v, \chi}).$$

*Proof.* By Lemma 9.3.1, we have

$$\Theta_{\rho_{\lambda}} = \varepsilon(\mathsf{G}_{\lambda}, \mathsf{T}_{\lambda}) \cdot R(G, S_{\lambda}, \theta_{\lambda}),$$

and so the claim follows from Lemmas 9.6.1 and 9.6.2.

### 10. Reduction formulae for character integrals

If G is a connected reductive f-group with Frobenius F, S is a maximal f-torus in G, and  $\theta \in \operatorname{Irr}(S^F)$ , then from [20, Thm 4.2] we have the reduction formula

(29) 
$$R_{\mathsf{S},\theta}^{\mathsf{G}}(x) = \sum_{\substack{g \in \mathsf{G}^F\\ {}^g\mathsf{S} \subset \mathsf{G}_s}} g_*\theta(s) \cdot Q_{g\mathsf{S}g^{-1}}^{\mathsf{G}_s}(u),$$

where  $x = su \in \mathsf{G}^F$  is the Jordan decomposition, and for any maximal f-torus  $\mathsf{S}_1 \subset \mathsf{G}_s$ , the normalized Green function  $Q_{\mathsf{S}_1}^{\mathsf{G}_s}$  is defined on all of  $\mathsf{G}^F$  by

(30) 
$$Q_{\mathsf{S}_{1}}^{\mathsf{G}_{s}}(h) := \begin{cases} \frac{1}{|\mathsf{G}_{s}^{F}|} R_{\mathsf{S}_{1},\theta_{1}}^{\mathsf{G}_{s}}(h) & \text{if } h \in \mathsf{G}_{s}^{F} \text{ and } h \text{ is unipotent} \\ 0 & \text{otherwise }, \end{cases}$$

the right side being independent of  $\theta_1 \in \operatorname{Irr}(S_1^F)$ .

In this section we prove an analogue of Equation (29) for our functions  $R(G, S, \theta)$ , using now the topological Jordan decomposition.

Fix a pair  $(S,\theta) \in \hat{\mathfrak{T}}(G)$ , and let  $\hat{\mathcal{T}}$  denote the  $G^F$ -orbit of  $(S,\theta)$ . For  $\gamma \in G_0^F \cap G^{\mathrm{rss}}$  with topological Jordan decomposition  $\gamma = \gamma_{\mathrm{s}} \gamma_{\mathrm{u}}$ , we define

$$\hat{\mathcal{T}}(\gamma_{\mathrm{s}}) := \{ (S', \theta') \in \hat{\mathcal{T}} : \gamma_{\mathrm{s}} \in S' \}$$

Then  $G_{\gamma_s}^F$  preserves  $\hat{\mathcal{T}}(\gamma_s)$ , and acts on  $\hat{\mathcal{T}}(\gamma_s)$  with finitely many orbits.

Our reduction formula for  $R(G, S, \theta)$  is as follows.

LEMMA 10.0.4. For  $\gamma = \gamma_s \gamma_u$  as above,

$$R(G, S, \theta)(\gamma) = \sum_{(S', \theta') \in \hat{T}(\gamma_{\mathrm{s}})/G_{\gamma_{\mathrm{s}}}^{F}} \theta'(\gamma_{\mathrm{s}}) \cdot R(G_{\gamma_{\mathrm{s}}}, S', 1)(\gamma_{\mathrm{u}}).$$

The proof of Lemma 10.0.4 will require some preliminary steps. Let J be the facet in  $\mathcal{A}(S)$  such that  $J^F = \mathcal{A}(S)^F$ , and let S be the image of  $S \cap G_J$  in  $G_J$ . Any compact element  $\delta \in S^F$  belongs to  $S \cap G_J$ , and we let  $\overline{\delta} \in S$  denote the image of  $\delta$ .

Applying Equation (30) with  $G = G_J$ ,  $s = \overline{\gamma}_s$ , and  $S_1 = S$ , we have the normalized Green function  $Q_S^{(G_J)_{\overline{\gamma}_s}}$  defined on all of  $G_J^F$ . We let  $\dot{Q}_S^{(G_J)_{\overline{\gamma}_s}}$  denote the natural inflation of  $Q_S^{(G_J)_{\overline{\gamma}_s}}$  to a function on  $G_J^F$ , extended by zero to the rest of  $G^F$ .

LEMMA 10.0.5. Let  $\gamma \in G_0^F$  be regular semisimple with  $\gamma_s \in S$ , and let  $L_{\gamma_s}$  be a compact open subgroup of  $G_{\gamma_s}$  with Haar measure di. Then the support of the function on  $G_{\gamma_s}^F$  given by

$$h \mapsto \int_{L_{\gamma_{\mathrm{s}}}} \dot{Q}_{\mathrm{S}}^{(\mathsf{G}_{J})_{\overline{\gamma}_{\mathrm{s}}}}(^{hi}\gamma_{\mathrm{u}}) \ di,$$

is compact modulo the center of  $G_{\gamma_s}^F$ .

*Proof.* The function  $Q_{\mathsf{S}}^{(\mathsf{G}_J)_{\overline{\gamma}_s}}$  on the unipotent set in  $(\mathsf{G}_J)_{\overline{\gamma}_s}$  is the restriction of  $R_{\mathsf{S},\theta}^{(\mathsf{G}_J)_{\overline{\gamma}_s}}$ , for any  $\theta \in \operatorname{Irr}_0(S^F)$ . Take  $\theta$  to be regular. Since  $\mathsf{S}$  is F-minisotropic in  $(\mathsf{G}_J)_{\overline{\gamma}_s}$ , the function  $\dot{R}_{\mathsf{S},\theta}^{(\mathsf{G}_J)_{\overline{\gamma}_s}}$  is a matrix coefficient of a supercuspidal representation of  $G_{\gamma_s}^F$ , constructed as in Section 4.4 with  $G^F$  there replaced by  $G_{\gamma_s}^F$ . Hence the function  $\dot{Q}_{\mathsf{S}}^{(\mathsf{G}_J)_{\overline{\gamma}_s}}$  is the restriction of a supercuspidal matrix coefficient to the compact topological unipotent set in  $G_{\gamma_s}^F$ . The result now follows from [26, Lemma 23, p. 59].

The restriction of  $\theta$  to  $S^F \cap G_J$  is the inflation of a character  $\theta_0 \in \operatorname{Irr}(\mathsf{S}^F)$ . Let  $\dot{\theta}$  denote the function on  $G^F$  defined by

$$\dot{\theta}(\delta) = \begin{cases} \theta_0(\bar{\delta}) & \text{if } \delta \in G_J^F \text{ and } \bar{\delta} \in \mathsf{S} \\ 0 & \text{otherwise.} \end{cases}$$

For each regular semisimple element  $\gamma \in G_0^F$ , define a locally constant function  $f_{\gamma}$  on  $G^F$  by

$$f_{\gamma}(g) := \dot{\theta}({}^{g}\gamma_{\mathrm{s}}) \cdot \dot{Q}_{\mathsf{S}}^{(\mathsf{G}_{J})_{\overline{g}\gamma_{s}}}({}^{g}\gamma_{\mathrm{u}}).$$

Note that  $f_{\gamma}$  is supported on the set  $E(\gamma_s, S)$  defined in Section 8, and is left-invariant under  $G_J^{+F}$ .

LEMMA 10.0.6. Let  $\gamma \in G_0^F$  be regular semisimple, and let  $L_{\gamma_s}$  be a compact open subgroup of  $G_{\gamma_s}$  with Haar measure di. Then the function  $\tau_{\gamma} \colon G^F \to \mathbb{C}$  defined by

$$\tau_\gamma(g):=\int_{L_{\gamma_{\rm s}}}f_\gamma(gi)\,di$$

is locally constant and compactly supported modulo  $Z^F$ .

*Proof.* Since  $\tau_{\gamma}(jg) = \tau_{\gamma}(g)$  for all  $j \in (G_J^+)^F$  and  $g \in G^F$ , it is clear that  $\tau_{\gamma}$  is locally constant.

Without loss of generality, we assume that  $\gamma \in G_J^F$  and  $\overline{\gamma}_s \in S$ . By Lemma 8.0.10, there is a lift of (J, S) in  $G_{\gamma_s}$ . Any such lift is *F*-minisotropic in *G*. It follows that the center of  $G_{\gamma_s}^F$  is compact modulo  $Z^F$ .

Choose a set  $D(\gamma_s, S)$  of representatives for the double cosets in

$$N(G,S)^F \setminus \tilde{D}(\gamma_{\rm s},S) / G_{\gamma_{\rm s}}^F$$

By Lemma 8.0.11 the set  $D(\gamma_{\rm s},S)$  is finite, and the support of  $\tau_{\gamma}$  is contained in

$$E(\gamma_{s}, S) = \coprod_{d \in D(\gamma_{s}, S)} G_{J}^{+F} N(G, S)^{F} dG_{\gamma_{s}}^{F}.$$

Since S is F-minisotropic, the group  $N(G,S)^F$  is compact modulo  $Z^F$ . It suffices therefore to show, for fixed  $d \in D(\gamma_s, S)$ , that the function  $h \mapsto \tau_{\gamma}(dh)$  on  $G_{\gamma_s}^F$  has compact support modulo the center of  $G_{\gamma_s}^F$ . This is Lemma 10.0.5 with  $\gamma$  there replaced by  ${}^d\gamma$ .

The key to the reduction formula is the following "localization" result.

LEMMA 10.0.7. Suppose  $\gamma \in G_0^F$  is regular semisimple and L is a compact open subgroup of  $G^F$ , and let  $L_{\gamma_s} = L \cap G_{\gamma_s}$ . Normalize Haar measures so that  $\max_{d\ell}(L) = \max_{di}(L_{\gamma_s}) = 1$ . Then the integrals

$$\int_{G^F/Z^F} dg^* \int_{L_{\gamma_{\rm s}}} f_{\gamma}(gi) \, di$$

and

$$\int_{G^F/Z^F} dg^* \int_L f_\gamma(gl) \ dd$$

both converge and are equal. Moreover, these integrals are independent of L.

*Proof.* The first integral is

$$\int_{G^F/Z^F} au_\gamma(g) \ dg^*.$$

Lemma 10.0.6 shows that this integral converges and allows us to rewrite it as

$$\begin{split} \int_{G^F/Z^F} \tau_{\gamma}(g) \ dg^* &= \int_{G^F/Z^F} \ dg^* \int_L \tau_{\gamma}(gl) \ dl \\ &= \int_{G^F/Z^F} \ dg^* \int_L \ dl \ \int_{L_{\gamma_s}} f_{\gamma}(gli) \ di \\ &= \int_{G^F/Z^F} \ dg^* \int_L \ f_{\gamma}(gl) \ dl, \end{split}$$

absorbing i into the integral over L.

To see that the integrals are independent of L, it suffices to show they are unchanged if we replace L by a compact open subgroup L' < L. We have

$$\int_{G^F/Z^F} dg^* \int_{L_{\gamma_{\mathrm{s}}}} f_{\gamma}(gl) \, dl = \int_{G^F/Z^F} dg^* \int_{L_{\gamma_{\mathrm{s}}}} dl \int_{(L')_{\gamma_{\mathrm{s}}}} f_{\gamma}(gll') \, dl'.$$

By Lemma 10.0.6 again, the integral over  $(L')_{\gamma_s}$  has compact support as a function on  $G^F/Z^F \times L_{\gamma_s}$ . Hence we may switch the integrals over  $G^F/Z^F$  and  $L_{\gamma_s}$ . The claim follows.

Now we can prove Lemma 10.0.4. From Equation (29), we have

$$\frac{\operatorname{meas}_{dg}(G_J^F)}{\operatorname{meas}_{dz}({}^0Z^F)}R(G,S,\theta)(\gamma) = \int_{G^F/Z^F} dg^* \int_L \dot{R}_{\mathsf{S},\theta}^{\mathsf{G}_J}({}^{gl}\gamma) \, dl$$
$$= \sum_{x \in G_J^F/G_J^{+F}} \int_{G^F/Z^F} dg^* \int_L f_\gamma(xgl) \, dl.$$

Absorbing x into the integral over  $G^F/Z^F$  and using Lemma 10.0.7, we get

$$\frac{\operatorname{meas}_{dg}(G_J^F)}{\operatorname{meas}_{dz}({}^0Z^F)}R(G,S,\theta)(\gamma) = |\mathsf{G}_J^F| \int_{G^F/Z^F} \, dg^* \, \int_{L_{\gamma_{\mathrm{s}}}} f_{\gamma}(gi) \, di$$

During the rest of this calculation only, we use the abbreviations

$$N := N(G, S)^F, \quad U := G_J^{+F}, \quad H = G_{\gamma_s}.$$

Let  $D(\gamma_{\rm s},S)$  be as in the proof of 10.0.6. The integral over  $L_{\gamma_{\rm s}}$  is supported on

$$E(\gamma_{\rm s},S) = \coprod_{d \in D(\gamma_{\rm s},S)} \coprod_{\bar{n} \in N/N_d} UndH^F/Z^F,$$

where  $N_d = {}^d H \cap N$ . Consequently, we have

(31) 
$$\frac{\operatorname{meas}_{dg}(G_J^F)}{\operatorname{meas}_{dz}({}^0Z^F)}R(G,S,\theta)(\gamma) = |\mathsf{G}_J^F| \sum_{d \in D(\gamma_{\mathrm{s}},S)} \sum_{\bar{n} \in N/N_d} \int_{UndH^F/Z^F} dg^* \int_{L_{\gamma_{\mathrm{s}}}} f_{\gamma}(gi) \, di.$$

Note that the map  $(d, \bar{n}) \mapsto (nd)^{-1} \cdot (S, \theta)$  induces a bijection

$$D(\gamma_{\rm s}, S) \times N/N_d \xrightarrow{\sim} \hat{\mathcal{T}}(\gamma_{\rm s})/H.$$

Hence the sum in Equation (31) matches the sum in Lemma 10.0.4.

Fix  $d \in D(\gamma_{\rm s}, S)$  and  $\bar{n} \in N/N_d$ , and set

$$J' = (nd)^{-1}J, \ U' = G_{J'}^{+F} = \operatorname{Ad}(nd)^{-1}U, \ (S', \theta') = (nd)^{-1} \cdot (S, \theta), \ \gamma'_{s} = {}^{nd}\gamma_{s}.$$

We then have

$$\int_{UndH^F/Z^F} dg^* \int_{L_{\gamma_{\mathrm{s}}}} f_{\gamma}(gi) \, di = \frac{\mathrm{meas}_{dg}(U)}{\mathrm{meas}_{dh}(H \cap U')} \int_{H^F/Z^F} dh^* \int_{L_{\gamma_{\mathrm{s}}}} f_{\gamma}(ndhi) \, di.$$

From the definitions,

$$f_{\gamma}(ndhi) = \dot{\theta}(\gamma'_{\rm s}) \cdot \dot{Q}_{\sf S}^{({\sf G}_J)_{\overline{\gamma'}_s}}(^{ndhi}\gamma_{\rm u}) = \dot{\theta}'(\gamma_{\rm s}) \cdot \dot{Q}_{\sf S'}^{({\sf G}_{J'})_{\overline{\gamma}_s}}(^{hi}\gamma_{\rm u})$$

As in the proof of Lemma 8.0.11, the projection  $H \cap G_{J'} \longrightarrow \mathsf{G}_{J'}$  allows us to identify

$$(\mathsf{G}_{J'})_{\overline{\gamma}_s} = \mathsf{H}_{J'},$$

so that

$$f_{\gamma}(ndhi) = \dot{\theta}'(\gamma_{\rm s}) \cdot \dot{Q}_{{\sf S}'}^{{\sf H}_{J'}}({}^{hi}\gamma_{\rm u}).$$

Since  $U = G_J^{+F}$  and  $H_{J'}^{+F} = H \cap U'$ ,

$$\int_{UndH^{F}/Z^{F}} dg^{*} \int_{L_{\gamma_{s}}} f_{\gamma}(gi) di$$
$$= \frac{\operatorname{meas}_{dg}(G_{J}^{+F})}{\operatorname{meas}_{dh}(H_{J'}^{+F})} \int_{H^{F}/Z^{F}} dh^{*} \int_{L_{\gamma_{s}}} \dot{\theta}'(\gamma_{s}) \cdot \dot{Q}_{\mathsf{S}'}^{\mathsf{H}_{J'}}({}^{hi}\gamma_{u}) di.$$

Since the center of H is contained in the F-minisotropic torus S', we conclude that Z is the group of K-rational points of the maximal k-split torus in the center of  $\mathbf{G}_{\gamma_s}$ . Hence, from the definition of R(H, S', 1), we have

$$|\mathbf{G}_J^F| \int_{UndH^F/Z^F} dg^* \int_{L_{\gamma_{\mathrm{s}}}} f_{\gamma}(gi) \, di = \frac{\mathrm{meas}_{dg}(G_J^F)}{\mathrm{meas}_{dz}({}^0Z^F)} \theta'(\gamma_{\mathrm{s}}) \cdot R(H, S', 1)(\gamma_{\mathrm{u}}).$$

Inserting this into Equation (31) completes the proof of Lemma 10.0.4.

10.1. Characters in a simple case. We illustrate Lemma 10.0.4 in the simple case where  $\gamma \in G_0^F$  is strongly regular and topologically semisimple. We have  $\gamma_s = \gamma$  and  $\gamma_u = 1$ .

Let  $\hat{\mathcal{T}} \subset \hat{\mathfrak{T}}(G)$  be a  $G^F$ -orbit. We write

$$R(G, \hat{T}) := R(G, S', \theta')$$

for any  $(S', \theta') \in \hat{\mathcal{T}}$ . Then  $\hat{\mathcal{T}}(\gamma)$  is nonempty if and only if  $(S, \theta) \in \hat{\mathcal{T}}$ , where  $S = G_{\gamma}$  and  $\theta \in \operatorname{Irr}_0(S^F)$ , in which case

$$\hat{\mathcal{T}}(\gamma) = \{ (S, n_*\theta) : n \in N(G, S)^F / S^F \}.$$

Since  $R(G_{\gamma}, S, 1)(1) = 1$ , Lemma 10.0.4 gives the formula

$$R(G, \hat{T})(\gamma) = \sum_{n \in N(G,S)^F/S^F} n_*\theta(\gamma)$$

if  $\hat{\mathcal{T}}(\gamma)$  is nonempty, and  $R(G, \hat{\mathcal{T}})(\gamma) = 0$  otherwise.

Return now to the situation of Section 9.6, with  $F = F_u$  etc. By Lemma 9.6.1,  $\hat{\mathcal{T}}$  contains

$$(S_{\lambda}, \theta_{\lambda}) = \operatorname{Ad}(q_{\lambda}) \cdot (T, \chi),$$

for some  $\lambda \in r^{-1}(\omega)$ . If S is not  $G^{F_u}$ -conjugate to  $S_{\lambda}$ , then  $R(G, \hat{T})(\gamma) = 0$ . Suppose  $S = {}^hS_{\lambda}$  for some  $h \in G^{F_u}$ . Let  $\theta = h_*\theta_{\lambda}$ , so that

$$\hat{\mathcal{T}}(\gamma) = \{(S, n_*\theta): n \in N(G, S)^{\mathcal{F}_u}/S\}.$$

From Lemmas 2.11.2 and 10.0.4 it follows that

$$R(G, \hat{\mathcal{T}})(\gamma) = \sum_{y \in W^{w\vartheta}_{o,\lambda}} (hq_{\lambda}y)_* \chi(\gamma).$$

From Lemma 9.3.1 we get the following character values.

PROPOSITION 10.1.1. Suppose  $\gamma \in G_0^{\mathcal{F}_u}$  is strongly regular and topologically semisimple. Then  $\Theta_{\rho_\lambda}(\gamma) = 0$  unless  $\gamma$  lies in a  $G^{\mathcal{F}_u}$ -conjugate of  $S_\lambda$ , and if  $\gamma \in {}^hS_\lambda$  for  $h \in G^{\mathcal{F}_u}$ ,

$$\Theta_{\rho_{\lambda}}(\gamma) = \varepsilon(\mathsf{G}_{\lambda},\mathsf{T}_{\lambda}) \sum_{y \in W_{o,\lambda}^{w\vartheta}} (hq_{\lambda}y)_{*}\chi(\gamma).$$

#### 11. Reduction formula for stable character integrals

In this section we prove the analogue of Lemma 10.0.4 for stable character integrals. Fix a *G*-stable class  $\hat{\mathcal{T}}_{st} \subset \hat{\mathfrak{T}}(G)$ . Recall from Lemma 9.4.3 that there is  $v \in N/T$  and  $\chi \in \operatorname{Irr}_0(T^{F_v})$  such that every pair  $(S, \theta) \in \hat{\mathcal{T}}_{st}$  is of the form

$$(S,\theta) = ({}^{g}T, g_{*}\chi)$$

for some  $g \in G$  with  $g^{-1}F(g) \in v$ .

Given  $\gamma \in G_0^F$  regular semisimple, with topological Jordan decomposition  $\gamma = \gamma_s \gamma_u$ , we define

$$\hat{\mathcal{T}}_{\mathrm{st}}(\gamma_{\mathrm{s}}) := \{ (S, \theta) \in \hat{\mathcal{T}}_{\mathrm{st}} : \gamma_{\mathrm{s}} \in S \}.$$

This set is a finite disjoint union

$$\hat{\mathcal{T}}_{\mathrm{st}}(\gamma_{\mathrm{s}}) = \prod_{\hat{i} \in \hat{I}(\gamma_{\mathrm{s}})} \hat{\mathcal{T}}_{\mathrm{st}}(\gamma_{\mathrm{s}}, \hat{i}),$$

where each  $\hat{T}_{st}(\gamma_s, \hat{i})$  is a  $G_{\gamma_s}$ -stable class in  $\hat{\mathfrak{T}}(G_{\gamma_s})$ , and  $\hat{I}(\gamma_s)$  is an index set for these  $G_{\gamma_s}$ -stable classes.

Applying  $p_1$ , we have

$$\mathcal{T}_{\mathrm{st}}(\gamma_{\mathrm{s}}) := p_1[\hat{\mathcal{T}}_{\mathrm{st}}(\gamma_{\mathrm{s}})] = \prod_{i \in I(\gamma_{\mathrm{s}})} \mathcal{T}_{\mathrm{st}}(\gamma_{\mathrm{s}}, i),$$

where each  $\mathcal{T}_{st}(\gamma_s, i)$  is a  $G_{\gamma_s}$ -stable class in  $\mathfrak{T}(G_{\gamma_s})$ , and  $I(\gamma_s)$  is an index set for these  $G_{\gamma_s}$ -stable classes. There is a surjective map  $\hat{i} \mapsto i$  from  $\hat{I}(\gamma_s)$  to  $I(\gamma_s)$ , such that

$$p_1[\mathcal{T}_{\mathrm{st}}(\gamma_{\mathrm{s}}, i)] = \mathcal{T}_{\mathrm{st}}(\gamma_{\mathrm{s}}, i).$$

The fiber of this map over  $i \in I(\gamma_s)$  has cardinality

$$N(i) := |N(G_{\gamma_{\mathrm{s}}}, S^F)/S|,$$

where S is any element of  $\mathcal{T}_{st}(\gamma_s, i)$ .

For any  $G_{\gamma_s}$ -stable class  $T^1_{\mathrm{st}} \subset \mathfrak{T}(G_{\gamma_s})$ , we set

$$Q(G_{\gamma_{\mathrm{s}}}, \mathcal{T}_{\mathrm{st}}^{1}) := \sum_{S \in \mathcal{T}_{\mathrm{st}}^{1}/G_{\gamma_{\mathrm{s}}}^{F}} |N(G_{\gamma_{\mathrm{s}}}, S^{F})/SN(G_{\gamma_{\mathrm{s}}}^{F}, S)| \cdot R(G_{\gamma_{\mathrm{s}}}, S, 1).$$

This will turn out to be a stable *p*-adic analogue of a Green function. We will consider the sums  $Q(G_{\gamma_s}, \mathcal{T}_{st}(\gamma_s, i))$ , for  $i \in I(\gamma_s)$ . But first we need more notation.

For each  $\hat{i} \in \hat{I}(\gamma_s)$  and  $S \in \mathcal{T}_{st}(\gamma_s, \hat{i})$ , we have a character sum

$$\theta_S^i = \sum_{\theta \in p_2^i(p_1^i)^{-1}(S)} \theta,$$

where  $p_1^{\hat{i}}$  (resp.  $p_2^{\hat{i}}$ ) is the restriction of  $p_1$  (resp.  $p_2$ ) to  $\hat{\mathcal{T}}_{st}(\gamma_s, \hat{i})$ .

In fact, this sum is independent of S: Given two tori  $S, S' \in \mathcal{T}_{st}(\gamma_s, i)$ , we have

$$\theta_S^{\hat{i}}(\gamma_{\rm s}) = \theta_{S'}^{\hat{i}}(\gamma_{\rm s}),$$

as a special case of Lemma 9.4.4. We therefore define

$$\theta_{\hat{i}}^{\chi}(\gamma_{\rm s}) := \theta_S^i(\gamma_{\rm s}),$$

for any  $S \in \mathcal{T}_{st}(\gamma_s, i)$ . Note that the sum

$$\theta_i^{\chi}(\gamma_{\rm s}) := \sum_{\hat{i} \mapsto i} \theta_{\hat{i}}^{\chi}(\gamma_{\rm s})$$

is none other than the character sum  $\theta_S^{\chi}(\gamma_s)$ , for any  $S \in \mathcal{T}_{st}(\gamma_s, i)$ , as defined in Section 9.4.

Finally, recall (Section 10) that for each  $G^F$ -orbit  $\hat{\mathcal{T}} \subset \hat{\mathcal{T}}_{st}$ , we have defined

$$\hat{\mathcal{T}}(\gamma_{\rm s}) = \{ (S, \theta) \in \hat{\mathcal{T}} : \gamma_{\rm s} \in S \}.$$

Now we are ready to state the reduction formula for stable character integrals.

LEMMA 11.0.2. For  $\gamma \in G_0^F$  regular semisimple, with topological Jordan decomposition  $\gamma = \gamma_s \gamma_u$ ,

$$R(G, \hat{\mathcal{T}}_{\mathrm{st}})(\gamma) = \sum_{i \in I(\gamma_{\mathrm{s}})} \frac{\theta_{i}^{\chi}(\gamma_{\mathrm{s}})}{N(i)} \cdot Q(G_{\gamma_{\mathrm{s}}}, \mathcal{T}_{\mathrm{st}}(\gamma_{\mathrm{s}}, i))(\gamma_{\mathrm{u}}).$$

*Proof.* Using Lemma 10.0.4, we compute

$$\begin{split} R(G,\hat{T}_{\mathrm{st}})(\gamma) &= \sum_{\hat{T}\in\hat{T}_{\mathrm{st}}/G^{F}} R(G,\hat{T})(\gamma) \\ &= \sum_{\hat{T}\in\hat{T}_{\mathrm{st}}/G^{F}} \sum_{(S,\theta)\in\hat{T}(\gamma_{\mathrm{s}})/G^{F}_{\gamma_{\mathrm{s}}}} \theta(\gamma_{\mathrm{s}}) \cdot R(G_{\gamma_{\mathrm{s}}},S,1)(\gamma_{\mathrm{u}}) \\ &= \sum_{\hat{i}\in\hat{I}(\gamma_{\mathrm{s}})} \sum_{(S,\theta)\in\hat{T}_{\mathrm{st}}(\gamma_{\mathrm{s}},\hat{i})/G^{F}_{\gamma_{\mathrm{s}}}} \theta(\gamma_{\mathrm{s}}) \cdot R(G_{\gamma_{\mathrm{s}}},S,1)(\gamma_{\mathrm{u}}) \\ &= \sum_{\hat{i}\in\hat{I}(\gamma_{\mathrm{s}})} \sum_{S\in\mathcal{T}_{\mathrm{st}}(\gamma_{\mathrm{s}},\hat{i})/G^{F}_{\gamma_{\mathrm{s}}}} \frac{\theta_{S}^{\hat{i}}(\gamma_{\mathrm{s}})}{|N(G^{F}_{\gamma_{\mathrm{s}}},S)/S^{F}|} \cdot R(G_{\gamma_{\mathrm{s}}},S,1)(\gamma_{\mathrm{u}}) \\ &= \sum_{i\in I(\gamma_{\mathrm{s}})} \theta_{i}^{\chi}(\gamma_{\mathrm{s}}) \sum_{S\in\mathcal{T}_{\mathrm{st}}(\gamma_{\mathrm{s}},\hat{i})/G^{F}_{\gamma_{\mathrm{s}}}} \frac{1}{|N(G^{F}_{\gamma_{\mathrm{s}}},S)/S^{F}|} \cdot R(G_{\gamma_{\mathrm{s}}},S,1)(\gamma_{\mathrm{u}}) \\ &= \sum_{i\in I(\gamma_{\mathrm{s}})} \frac{\theta_{i}^{\chi}(\gamma_{\mathrm{s}})}{N(i)} \cdot Q(G_{\gamma_{\mathrm{s}}},\mathcal{T}_{\mathrm{st}}(\gamma_{\mathrm{s}},i))(\gamma_{\mathrm{u}}). \end{split}$$

11.1. A bijection between stable classes of unramified tori. Lemma 11.0.2 reduces the proof of stability to the topologically unipotent set, as follows. Let  $\mathcal{T}_{\rm st}(\gamma_{\rm s})/G_{\gamma_{\rm s}}$  denote the set of  $G_{\gamma_{\rm s}}$ -stable classes in  $\mathcal{T}_{\rm st}(\gamma_{\rm s})$ . So  $\mathcal{T}_{\rm st}(\gamma_{\rm s})/G_{\gamma_{\rm s}}$  is indexed by  $I(\gamma_{\rm s})$ .

We now assume that  $\gamma \in G_0^F$  is in fact strongly regular semisimple; that is, the centralizer of  $\gamma$  in **G** is a torus. Then if  $g \in G$  and  ${}^g\gamma$  is again in  $G^F$ ,

we can construct a bijection

$$\iota_g: \mathcal{T}_{\mathrm{st}}(\gamma_{\mathrm{s}})/G_{\gamma_{\mathrm{s}}} \xrightarrow{\sim} \mathcal{T}_{\mathrm{st}}({}^g\gamma_{\mathrm{s}})/G_{{}^g\gamma_{\mathrm{s}}}$$

as follows. Let  $S \in \mathcal{T}_{st}(\gamma_s)$ . Since  $\gamma \in G^F$  and has connected centralizer,  $g^{-1}F(g) \in Z^1(F, G_{\gamma_s})$ .

Let  $\mathbf{Z}_{\gamma_s}$  be the maximal k-split torus in the center of  $\mathbf{G}_{\gamma_s}$ . Since S is *F*-minisotropic in  $G_{\gamma_s}$ , the group of co-invariants of F in  $X_*(\mathbf{S})$  has the same rank as  $X_*(\mathbf{Z}_{\gamma_s})$ . It then follows from [35, Thm.1.2] (see also Lemma 2.6.1) that the map  $H^1(F, S) \longrightarrow H^1(F, G_{\gamma_s})$  is surjective.

This means there is  $h \in G_{\gamma_s}$  such that  $(gh)^{-1}F(gh) \in S$ . Hence  $\operatorname{Ad}(gh) : S \longrightarrow {}^{gh}S$  commutes with F, so that  ${}^{gh}S \in \mathcal{T}_{\operatorname{st}}({}^{g}\gamma_s)$ .

Suppose also  $S' \in \mathcal{T}_{st}(\gamma_s)$ , and  $(S')^F = {}^k(S^F)$  for some  $k \in G_{\gamma_s}$ . This implies that  $k^{-1}F(k) \in S$ . As above, there exists  $h' \in G_{\gamma_s}$  such that  $(gh')^{-1}F(gh') \in S'$ . Then the element  $j := gh'kh^{-1}g^{-1} \in G_{g\gamma_s}$  satisfies  $j^{-1}F(j) \in {}^{gh}S$ ,  ${}^{jgh}S = {}^{gh'}S'$ , which means that  ${}^{gh}S$  is  $G_{g\gamma_s}$ -stably conjugate to  ${}^{gh'}S'$ . Therefore, sending the  $G_{\gamma_s}$ -stable class of S to the  $G_{g\gamma_s}$ -stable class of  ${}^{gh}S$  gives a well-defined injection  $\iota_g$ , as above. It is straightforward to check that  $\iota_{(g^{-1})}$  is the inverse of  $\iota_q$ , so that  $\iota_q$  is actually a bijection.

We may view  $\iota_g$  as a bijection on index sets:

$$\iota_g: I(\gamma_s) \longrightarrow I({}^g\gamma_s).$$

This map has the property that

$$N(i) = N(\iota_q(i)),$$

for each  $i \in I(\gamma_s)$ .

LEMMA 11.1.1. Let  $\gamma \in G_0^F$  be strongly regular semisimple, with topological Jordan decomposition  $\gamma = \gamma_s \gamma_u$ , and let  $g \in G$  be such that  ${}^g \gamma \in G^F$ . Let  $\hat{T}_{st}$  be a G-stable class in  $\hat{\mathfrak{T}}(G)$ , and assume that for all  $i \in I(\gamma_s)$ ,

$$Q(G_{\gamma_{s}}, \mathcal{T}_{st}(\gamma_{s}, i))(\gamma_{u}) = Q(G_{g\gamma_{s}}, \mathcal{T}_{st}(g\gamma_{s}, \iota_{g}(i)))(g\gamma_{u})$$

Then

$$R(G, \hat{\mathcal{T}}_{\mathrm{st}})(\gamma) = R(G, \hat{\mathcal{T}}_{\mathrm{st}})({}^{g}\gamma).$$

Proof. From Lemma 11.0.2,

(32) 
$$R(G, \hat{\mathcal{T}}_{st})(\gamma) = \sum_{i \in I(\gamma_s)} \frac{\theta_i^{\chi}(\gamma_s)}{N(i)} \cdot Q(G_{\gamma_s}, \mathcal{T}_{st}(\gamma_s, i))(\gamma_u).$$

On the other hand, by Lemma 9.4.4 again (this time in full force),

$$\theta_i^{\chi}(\gamma_{\rm s}) = \theta_{\iota_q(i)}^{\chi}({}^g\gamma_{\rm s}),$$

It follows that

(33) 
$$R(G,\hat{\mathcal{I}}_{st})({}^{g}\gamma) = \sum_{i \in I(\gamma_{s})} \frac{\theta_{i}^{\chi}(\gamma_{s})}{N(i)} \cdot Q(G_{{}^{g}\gamma_{s}},\mathcal{I}_{st}({}^{g}\gamma_{s},\iota_{g}(i)))({}^{g}\gamma_{u}),$$

whence the result.

11.2. Stable characters in a simple case. We illustrate Section 11.1 by considering the stable version of Section 10.1. As in the latter section, we suppose  $\gamma \in G^F$  is strongly regular and topologically semisimple, and let  $S = G_{\gamma}$ . Let  $\hat{\mathcal{T}}_{st} \subset \hat{\mathfrak{T}}(G)$  be a G-stable class.

We describe the objects in 11.0.2 in this case. If  $\hat{T}_{st}(\gamma)$  is empty, then  $R(G, \hat{T}_{st})(\gamma) = 0$ . Assume  $\hat{T}_{st}(\gamma)$  is nonempty. Then there is  $\theta \in \operatorname{Irr}_0(S^F)$  such that

$$\hat{\mathcal{T}}_{\mathrm{st}}(\gamma) = \{ (S, n_*\theta) : n \in N(G, S^F) / S \}$$

Thus, we may identify  $\hat{I}(\gamma) = N(G, S^F)/S$ , and for each  $n \in \hat{I}(\gamma)$ ,

$$\widetilde{T}_{\mathrm{st}}(\gamma, n) = \{(S, n_*\theta)\}$$

The index set  $I(\gamma)$  consists of a single element, *i*, and

$$Q(G_{\gamma}, \mathcal{T}_{\mathrm{st}}(\gamma, i))(\gamma_{\mathrm{u}}) = Q(S, \{S\})(1) = 1.$$

In terms of tori, the map  $\iota_g$  simply sends S to  ${}^gS$ . Hence the conditions of Lemma 11.1.1 hold trivially, so that  $R(G, \hat{\mathcal{T}}_{st})$  is constant on the G-stable class of  $\gamma$ .

Lemma 11.0.2 gives the formula

$$R(G, \hat{T}_{\mathrm{st}})(\gamma) = \sum_{n \in N(G, S^F)/S} n_* \theta(\gamma).$$

From Lemma 9.6.3 it follows that the sum of characters in the *L*-packet  $\Pi(\varphi, \omega)$  is constant on the *G*-stable class of  $\gamma$ .

### 12. Transfer to the Lie algebra

Lemma 11.1.1 reduces the proof of stability to the following.

LEMMA 12.0.1. Assume as above that  $\gamma \in G_0^F$  is strongly regular semisimple, and  $g \in G$  is such that  ${}^g \gamma \in G^F$ . Let  $\mathcal{T}_{st}$  be a  $G_{\gamma_s}$ -stable class in  $\mathfrak{T}(G_{\gamma_s})$ . Then

$$Q(G_{\gamma_{\mathrm{s}}}, \mathcal{T}_{\mathrm{st}})(\gamma_{\mathrm{u}}) = Q(G_{g_{\gamma_{\mathrm{s}}}}, \iota_g \mathcal{T}_{\mathrm{st}})({}^g \gamma_{\mathrm{u}}).$$

We will prove Lemma 12.0.1 under some restrictions on k, to be installed as they are needed. The first step in the proof of Lemma 12.0.1 is to transfer the calculation to the Lie algebras  $\mathfrak{g}_{\gamma_s}$  and  $\mathfrak{g}_{g\gamma_s}$  of  $G_{\gamma_s}$  and  $G_{g\gamma_s}$  respectively. We then invoke a deep result of Waldspurger [63], which states that, for groups

which are inner forms of each other, the fundamental lemma for the Lie algebra is true.

12.1. Orbital Integrals. Fix  $\gamma$  and g as in the statement of Lemma 12.0.1. Since the calculation takes place mostly in the groups  $G_{\gamma_s}$  and  $G_{{}^g\gamma_s}$ , we adjust the notation slightly for clarity. Let  $H = G_{\gamma_s}$ , and let  $\mathfrak{h} = \text{Lie}(H)$  be the Lie algebra of H. We fix an additive character  $\Lambda : k \longrightarrow \mathbb{C}^{\times}$  which is trivial on the prime ideal of R but nontrivial on R. Suppose B is a nondegenerate, symmetric,  $\langle F \rangle \ltimes H$ -invariant bilinear form on  $\mathfrak{h}$ . For  $f \in C_c^{\infty}(\mathfrak{h}^F)$ , the space of locally constant, compactly supported functions on  $\mathfrak{h}^F$ , we define the Fourier transform (with respect to B) of f by

$$\hat{f}(X) = \int_{\mathfrak{h}^F} f(Y) \cdot \Lambda(B(X,Y)) \, dY,$$

where dY is Haar measure on  $\mathfrak{h}$ , normalized as in Section 5.

Suppose X is a regular semisimple element of  $\mathfrak{h}^F$ . For  $f \in C_c^{\infty}(\mathfrak{h}^F)$  we define  $\mu_X^{H^F}(f)$ , the orbital integral of f with respect to X, by

$$\mu_X^{H^F}(f) := \int_{H^F/(C'_H(X))^F} f({}^hX) \, \frac{dh}{dt}$$

where  $C'_H(X)$  is the maximal unramified torus in the torus  $C_H(X)$  and dh, dt are Haar measures on  $H^F$ ,  $C'_H(X)^F$ , respectively, normalized as in Section 5.

Remark 12.1.1. If  $X' \in \mathfrak{h}^F$  is *H*-conjugate to *X*, then the tori  $C'_H(X)$  and  $C'_H(X')$  are *H*-conjugate. Consequently, if dt' denotes the Haar measure on  $C'_H(X')$ , it follows that the measures  $\frac{dh}{dt}$  and  $\frac{dh}{dt'}$  determine the same multiple of the top degree form on the orbit  $^{\mathbf{H}}X = ^{\mathbf{H}}X'$ .

We define  $\hat{\mu}_X^{H^F}(f) := \mu_X^{H^F}(\hat{f})$  for  $f \in C_c^{\infty}(\mathfrak{h}^F)$ . In this way, we have a distribution  $\hat{\mu}_X^{H^F}$  on  $C_c^{\infty}(\mathfrak{h}^F)$ . Thanks to Harish-Chandra [25, Th. 4.4], we know that  $\hat{\mu}_X^{H^F}$  is represented on  $\mathfrak{h}^F$  by a function, which we also denote by  $\hat{\mu}_X^{H^F}$ . (The same result is true for the Fourier transform of any orbital integral.)

12.2. A result of Waldspurger. In this section, **H** is any connected reductive k-group splitting over K. As usual, F is the Frobenius action on both  $H := \mathbf{H}(K)$ , and  $\mathfrak{h} := \text{Lie}(H)$ . For  $X \in \mathfrak{h}^F$  regular semisimple, write

$$[\mathrm{Ad}(H)X]^F = \coprod_i \mathrm{Ad}(H^F)X_i$$

where the  $X_i$  run over a (finite) set of representatives for the  $\mathrm{Ad}(H^F)$ -orbits in  $[\mathrm{Ad}(H)X]^F$  (see §2.9.1). We set

$$\hat{S}_X^{\mathfrak{h}} = \sum_i \hat{\mu}_{X_i}^{H^F}.$$

The measures used for each orbital integral are compatible, in the sense of Remark 12.1.1.

Let  $\mathbf{H}^*$  denote a k-quasi-split inner form of  $\mathbf{H}$ , and let  $\mathbf{H}^*_{ad}$  be the adjoint group of  $\mathbf{H}^*$ . Let  $H^*$  and  $H^*_{ad}$  denote the groups of K-rational points of  $\mathbf{H}^*$ and  $\mathbf{H}^*_{ad}$ , respectively, and let  $F^*$  denote the action of Frobenius on  $H^*$ ,  $H^*_{ad}$ and  $\mathfrak{h}^* = \text{Lie}(H^*)$ . Choose an inner twist

$$\phi \colon H \to H^*.$$

That is,  $\phi$  is a K-isomorphism, and there is  $h_{\phi}^* \in H_{ad}^*$  such that

$$\operatorname{Ad}(h_{\phi}^*) = F^* \circ \phi \circ F^{-1} \circ \phi^{-1} \in \operatorname{Aut}_K(H^*).$$

Here we implicitly use the isomorphism  $H^1(F, H_{ad}) = H^1(k, \mathbf{H}_{ad})$ ; see Section 2.2. The choice of  $\phi$  defines an injective map  $S_{\phi}$  from the set of stable regular semisimple orbits in  $\mathfrak{h}^F$  to the set of stable regular semisimple orbits in  $(\mathfrak{h}^*)^{F^*}$ , as follows. If  $X \in \mathfrak{h}^F$ , then  $F^*(d\phi(X)) = \operatorname{Ad}(h_{\phi}^*)d\phi(X)$ , so that the  $\operatorname{Ad}(H^*)$ -orbit of  $d\phi(X)$  is  $F^*$ -stable. If X is regular semisimple, then so too is  $d\phi(X)$ . The existence of an  $F^*$ -stable Kostant section shows that the  $\operatorname{Ad}(H^*)$ -orbit of  $d\phi(X)$  contains an  $F^*$ -fixed point  $X^*$  (see, for example, [56, 9.5] or [36]). Finally,  $S_{\phi}$  sends  $[\operatorname{Ad}(H)X]^F$  to  $[\operatorname{Ad}(H^*)X^*]^{F^*}$ .

Suppose now that  $\mathbf{H}'$  is any inner form of  $\mathbf{H}$ . Let H' denote the group of K-rational points of  $\mathbf{H}'$  and let F' denote the action of Frobenius on H'and  $\mathfrak{h}' = \operatorname{Lie}(H')$ . Suppose  $X \in \mathfrak{h}^F$  and  $X' \in (\mathfrak{h}')^{F'}$  are regular semisimple elements, and  $\phi: H \to H^*$  and  $\phi': H' \to H^*$  are inner twists. We say that Xand X' are  $(\phi, \phi')$ -comparable provided that

$$S_{\phi}([\operatorname{Ad}(H)X]^F) = S_{\phi'}([\operatorname{Ad}(H')X']^{F'})$$

as stable regular semisimple orbits in  $(\mathfrak{h}^*)^{F^*}$ .

Example 12.2.1. Take  $\mathbf{H} = \mathbf{G}_{\gamma_s}$  as in the situation of Section 12.1. Let log:  $G_{0^+} \to \mathfrak{g}$  be any injective  $\langle F \rangle \ltimes G$ -equivariant map which takes regular semisimple elements to regular semisimple elements. (The existence of such a map with just these properties follows from [9, p. 333, §7.6, Prop. 10].) Then  $C_{\mathbf{G}}(\gamma)$  is a torus in  $\mathbf{H}$ , and F(g) = gs for some  $s \in C_H(\gamma)$ . Moreover,  $\mathrm{Ad}(g) : H \longrightarrow H' := {}^{g}H$  is an inner twist, with F' = F. Let  $X := \log(\gamma_u)$ . From [29, Th. 13.4(a)] it follows that  $X \in \mathfrak{h}$  and  ${}^{g}X \in {}^{g}\mathfrak{h}$  are regular semisimple elements. Since F and  $\mathrm{Ad}(s)$  fix  $\gamma_u$ , it follows that F(X) = X, and  $F({}^{g}X) = {}^{g}X$ .

Suppose  $\phi: H \to H^*$  is an inner twist, and let  $X^* \in [\operatorname{Ad}(H^*)d\phi(X)]^{F^*}$ . One checks that the map  $\phi' := \phi \circ \operatorname{Ad}(g^{-1}): {}^{g}H \to H^*$  is also an inner twist, and that  $X^* \in [\operatorname{Ad}(H^*)d\phi'({}^{g}X)]^{F^*}$ . It follows that X and  ${}^{g}X$  are  $(\phi, \phi')$ -comparable.

*Example* 12.2.2. Continue with the notation of Example 12.2.1 and also Section 11.1. Let  $\mathcal{T}_{st}$  be an *H*-stable class in  $\mathfrak{T}(H)$ , and let  $\mathcal{T}'_{st} = \iota_g \mathcal{T}_{st}$ , an

H'-stable class in  $\mathfrak{T}(H')$ , be as in Section 11.1. Suppose  $S_0 \in \mathcal{T}_{st}$  and  $X_0$  is a  $\mathfrak{g}$ -regular element of  $\operatorname{Lie}(S_0)^F$ . Let  $X \in [\operatorname{Ad}(H)X_0]^F$ . Note that X is regular in  $\mathfrak{g}$ . As in the definition of  $\iota_g$ , there is  $h \in H$  such that  $(gh)^{-1}F(gh) \in C_G(X)$ , and the elements X and  $X' := {}^{gh}X \in [\operatorname{Ad}(H')({}^{g}X_0)]^F$  are  $(\phi, \phi \circ \operatorname{Ad}(g)^{-1})$ -comparable.

LEMMA 12.2.3. Let  $\phi: H \to H^*$  and  $\phi': H' \to H^*$  denote inner twists. Suppose X, Y (resp. X', Y') are regular semisimple elements in  $\mathfrak{h}^F$  (resp.  $(\mathfrak{h}')^{F'}$ ). If X and X' are  $(\phi, \phi')$ -comparable elliptic elements and Y and Y' are  $(\phi, \phi')$ -comparable elements, then

$$\hat{S}^{\mathfrak{h}}_{X}(Y) = \varepsilon(\mathbf{H}, \mathbf{H}') \cdot \hat{S}^{\mathfrak{h}'}_{X'}(Y').$$

*Remark* 12.2.4. The above lemma may be viewed as more evidence for Kottwitz' sign conjecture [33].

*Proof.* Without loss of generality,  $\mathbf{H}'$  is k-quasi-split, and we may replace  $\mathbf{H}'$  by  $\mathbf{H}^*$ . Waldspurger has already shown [63, Th. 1.5] that for X, Y, X', Y' as in the statement of the lemma,

$$\hat{S}^{\mathfrak{h}}_X(Y) = c \cdot \hat{S}^{\mathfrak{h}^*}_{X'}(Y')$$

where c is an eighth root of unity. (In the notation of [63], this is actually the special case  $s = 1, \xi = I$  of [63, Th. 1.5], and  $c = \gamma_{\Lambda}(\mathfrak{h}^*)/\gamma_{\Lambda}(\mathfrak{h})$ .) We will give two proofs that  $c = \varepsilon(\mathbf{H}, \mathbf{H}^*)$ .

The first proof uses Shalika germs. For all  $n \in \mathbb{Z}$  we have

$$\hat{S}^{\mathfrak{h}}_X(\varpi^n Y) = c \cdot \hat{S}^{\mathfrak{h}^*}_{X'}(\varpi^n Y').$$

From Harish-Chandra [25, Th. 5.1.1], for all  $n \in \mathbb{Z}$  sufficiently large,

$$\hat{S}_{X}^{\mathfrak{h}}(\varpi^{2n}Y) = \sum_{\mathcal{O}\in\mathcal{O}_{\mathfrak{h}}(0)} c_{\mathcal{O}}^{\mathfrak{h}}(X) \cdot \hat{\mu}_{\mathcal{O}}(\varpi^{2n}Y)$$
$$= c_{0}^{\mathfrak{h}}(X) + \sum_{\mathcal{O}\in\mathcal{O}_{\mathfrak{h}}(0)\setminus\{0\}} c_{\mathcal{O}}^{\mathfrak{h}}(X) \cdot q^{-n \cdot \dim\mathcal{O}} \cdot \hat{\mu}_{\mathcal{O}}(Y)$$

where  $\mathcal{O}_{\mathfrak{h}}(0)$  denotes the set of nilpotent  $H^F$ -orbits in  $\mathfrak{h}^F$ , the  $c_{\mathcal{O}}^{\mathfrak{h}}(X)$  are complex constants, and 0 denotes the zero orbit  $\{0\}$ . A similar statement is true for  $\hat{S}_{X'}^{\mathfrak{h}^*}$ . Thus,

$$c^{\mathfrak{h}}_{0}(X) = \lim_{n \to \infty} \hat{S}^{\mathfrak{h}}_{X}(\varpi^{2n}Y) = \lim_{n \to \infty} c \cdot \hat{S}^{\mathfrak{h}^{*}}_{X'}(\varpi^{2n}Y') = c \cdot c^{\mathfrak{h}^{*}}_{0}(X').$$

Let  $X_1, X_2, \ldots, X_m$  be representatives for the  $H^F$ -orbits in  $[\mathrm{Ad}(H)X]^F$ . From [25, Th. 8.1] we have

$$c_0^{\mathfrak{h}}(X) = \sum_{j=1}^m \Gamma_0^{C_{\mathfrak{h}}(X_j)}(X_j),$$

where  $\Gamma_0^{C_b(X_j)}(X_j)$  denotes the evaluation of the (unnormalized) Shalika germ corresponding to the zero orbit at  $X_j$ .

If the center of  $H^F$  is compact, then so too is the center of  $(H^*)^{F^*}$ . Thanks to Rogawski [49] we have

$$\Gamma_0^{C_{\mathfrak{h}}(X_j)}(X_j) = \frac{\varepsilon(\mathbf{H}, \mathbf{Z})}{\operatorname{Deg}(\operatorname{St}^H)}.$$

Thus, if the center of  $H^F$  is compact, we conclude from the above, the fact that  $\text{Deg}(\text{St}^H) > 0$ , and the fact that c is an eighth root of unity that  $c = \varepsilon(\mathbf{H}, \mathbf{H}^*)$ .

Suppose that the center  $Z^F$  of  $H^F$  is not compact. Let  $\mathbf{H}_d$  denote the derived group of  $\mathbf{H}$  and let  $\mathfrak{h}_d$  denote the Lie algebra of  $H_d = \mathbf{H}_d(K)$ . The center of  $H_d$  is finite and  $H^F/(H_d^F)Z^F$  is a finite group. Without loss of generality, we assume  $X \in \mathfrak{h}_d^F$ . From Lemma 2.9.1, we have that two regular semisimple elements of  $\mathfrak{h}_d^F$  are H-stably conjugate if and only if they are  $H_d$ -stably conjugate. However, since two regular semisimple elements of  $\mathfrak{h}_d^F$  may be  $H^F$ -conjugate without being  $H_d^F$ -conjugate, for  $1 \leq i \leq m$  we introduce the group

 $H_i^F := \{h \in H^F : \text{ there is an } h' \in H_d^F \text{ such that } {}^{h'h}X_i = X_i\}.$ 

We have  $H_d^F Z^F riangleq H_i^F riangleq H^F$ . Thus, we can write

$$\hat{S}^{\mathfrak{h}_d}_X = \sum_{i=1}^m \sum_{\bar{h} \in H^F/H^F_i} \hat{\mu}^{H^F_d}_{{}^{h^{-1}}X_i}$$

Suppose we can show that the restriction of  $\hat{S}^{\mathfrak{h}}_X$  to  $\mathfrak{h}^F_d$  equals  $e \cdot \hat{S}^{\mathfrak{h}_d}_X$  for some constant e > 0. We would then have  $c_0^{\mathfrak{h}}(X) = e \cdot c_0^{\mathfrak{h}_d}(X)$ . Arguing as in the previous paragraph, we would again conclude that  $c = \varepsilon(\mathbf{H}, \mathbf{H}^*)$ .

To complete the proof, we now show that such a constant e exists. We use Harish-Chandra's integral formula for the Fourier transform of a regular semisimple orbital integral [25, Lemma 7.9]. Since we only wish to establish the positivity of e, in what follows we are not careful about specifying our invariant measures nor about accounting for the (positive) constants that occur. Let Lbe a compact open subgroup of  $H^F$  which lies in  $H_d^F Z^F$ . There is a positive constant, const, so that for regular semisimple  $Y \in \mathfrak{h}_d^F$ 

$$\hat{S}_X^{\mathfrak{h}}(Y) = \operatorname{const} \cdot \sum_i \int_{H^F/Z^F} dg^* \int_L \Lambda(B({}^{g\ell}Y, X_i)) d\ell$$
$$= \operatorname{const} \cdot \sum_i \sum_{\bar{h} \in H^F/H^F_i} \sum_{\bar{g}_1 \in H^F_i/H^F_d Z^F}$$
$$\cdot \int_{H^F_d Z^F/Z^F} dg_2^* \int_L \Lambda(B({}^{g_1g_2\ell}Y, {}^{h^{-1}}X_i)) d\ell$$

which, from the definition of  $H_i^F$ , becomes

$$= \operatorname{const} \cdot \sum_{i} \sum_{\bar{h} \in H^{F}/H_{i}^{F}} |H_{i}^{F}/H_{d}^{F}Z^{F}| \cdot \int_{H_{d}^{F}Z^{F}/Z^{F}} dg_{2}^{*}$$
$$\cdot \int_{L} \Lambda(B(g_{2}\ell Y, h^{-1}X_{i})) d\ell.$$

We claim that for  $1 \leq i, j \leq m$ ,

$$\left|H_i^F/H_d^FZ^F\right| = \left|H_j^F/H_d^FZ^F\right|.$$

In fact, we will show that the group  $H_i^F$  is independent of i. Note that  $H_i^F/H_d^F Z^F$  can be characterized as the set of cosets in  $H^F/H_d^F Z^F$  which intersect  $(C_H(X_i))^F$  nontrivially. Thus, it is enough to show that for  $h \in H^F$ ,

$$h(H_d^F Z^F) \cap (C_H(X_i))^F \neq \emptyset \iff h(H_d^F Z^F) \cap (C_H(X_j))^F \neq \emptyset.$$

Suppose  $h \in H^F$  and  $g \in H^F_d Z^F$  so that  $hg \in (C_H(X_i))^F$ . It is enough to produce a  $g' \in H^F_d Z^F$  such that  $hg' \in (C_H(X_j))^F$ . Since  $X_i$  and  $X_j$  are  $H_d$ -stably conjugate, there is an  $h' \in H_d$  so that  $h'X_i = X_j$ . Since  $C_H(X_i)$  is abelian, this implies that  $h'((C_H(X_i))^F) = (C_H(X_j))^F$ . Consequently,  $h'(hg) \in (C_H(X_j))^F$  and  $h'(hg) = h(h^{-1}h'hg(h')^{-1}) \in hH_dZ^F$ . Set  $g' := (h^{-1}h'hg(h')^{-1})$ . Note that  $g \in H^F_d Z^F$  implies  $g' \in H_d(Z^F)$ . But also  $g' \in h^{-1}(C_H(X_j))^F \subset H^F$ , so in fact  $g' \in H^F_d Z^F$  and  $hg' \in (C_H(X_j))^F$ , as desired.

Therefore,

$$\hat{S}_X^{\mathfrak{h}}(Y) = \operatorname{const}' \cdot \sum_i \sum_{\bar{h} \in H^F/H_i^F} \int_{H_d^F Z^F/Z^F} dg_2^* \int_L \Lambda(B(^{g_2\ell}Y, ^{h^{-1}}X_i)) d\ell$$
$$= \operatorname{const}' \cdot \sum_i \sum_{\bar{h} \in H^F/H_i^F} \int_{H_d^F/(H_d^F \cap Z^F)} dg_2^* \int_L \Lambda(B(^{g_2\ell}Y, ^{h^{-1}}X_i)) d\ell. \quad \Box$$

12.3. Another calculation of Waldspurger's sign. In this section we give a second proof of Lemma 12.2.3 in terms of our pure inner forms  $G_{\lambda}$ . This proof continues in the vein of [63].

For  $\lambda \in X_w$ , we have a pure inner form  $\mathbf{G}_{\lambda}$  of  $\mathbf{G}$  with Frobenius  $F_{\lambda} = \operatorname{Ad}(u_{\lambda}) \circ F$ . In particular  $\mathbf{G} = \mathbf{G}_0$  is k-quasi-split. Note that  $\mathbf{G}_{\lambda} = \mathbf{G}$  as groups; the subscript indicates the variation in k-structure. To simplify the notation, we write  $\sigma := w\vartheta$ , and set  $\Sigma := \langle \sigma \rangle$ .

We define an inner twisting  $\phi_{\lambda} : \mathbf{G}_{\lambda} \longrightarrow \mathbf{G}_{0}$  by  $\phi_{\lambda} = \mathrm{Ad}(h_{\lambda})$ , where  $h_{\lambda} = p_{0}p_{\lambda}^{-1}$  and  $p_{\lambda}, p_{0} \in G$  satisfy the equations

(34) 
$$p_0^{-1} \operatorname{F}(p_0) = \dot{w}, \qquad p_\lambda^{-1} u_\lambda \operatorname{F}(p_\lambda) = t_\lambda \dot{w}$$

of Chapter 2.7. Let  $\Phi(\mathbf{T})$  denote the set of roots of  $\mathbf{T}$  in  $\mathbf{G}$ . Likewise, let  $\mathbf{T}_{\lambda} = \operatorname{Ad}(p_{\lambda})\mathbf{T}$ , and let  $\Phi(\mathbf{T}_{\lambda})$  denote the set of roots of  $\mathbf{T}_{\lambda}$  in  $\mathbf{G}_{\lambda}$ .

The map  $\operatorname{Ad}(p_{\lambda}) : \mathbf{T} \longrightarrow \mathbf{T}_{\lambda}$  intertwines  $F_w$  on  $\mathbf{T}$  with  $F_{\lambda}$  on  $\mathbf{T}_{\lambda}$ . It induces a map  $\Phi(\mathbf{T}) \longrightarrow \Phi(\mathbf{T}_{\lambda})$  given by

$$\alpha \mapsto \alpha_{\lambda} := \alpha \circ \operatorname{Ad}(p_{\lambda})^{-1},$$

satisfying

$$\mathbf{F}_{\lambda} \cdot \alpha_{\lambda} = (\sigma \cdot \alpha)_{\lambda}.$$

(Recall that  $F_w$  acts on  $\Phi(\mathbf{T})$  via  $\sigma$ .)

Fix  $\lambda \in X_w$ . By Hilbert's Theorem 90, there exists a set  $\{E_{\alpha_{\lambda}} : \alpha \in \Phi(\mathbf{T})\}$  of  $\mathbf{T}_{\lambda}$ -root vectors in  $\mathfrak{g}$  having the property that

$$\mathbf{F}_{\lambda} \cdot E_{\alpha_{\lambda}} = E_{(\sigma \cdot \alpha)_{\lambda}}.$$

The transformed root vectors

$$E_{\alpha}^* := \phi_{\lambda}(E_{\alpha_{\lambda}})$$

are only preserved by F up to scalar multiples. That is, for each  $\alpha \in \Phi(\mathbf{T})$  there is  $c_{\alpha_{\lambda}} \in \bar{k}$  such that

$$\mathbf{F}(c_{\alpha_{\lambda}}E_{\alpha}^{*}) = c_{(\sigma \cdot \alpha)_{\lambda}}E_{\sigma \cdot \alpha}^{*}.$$

A straightforward computation shows, for each  $\alpha \in \Phi(\mathbf{T})$ , that

(35) 
$$\operatorname{Frob}(c_{\alpha_{\lambda}}) = \varpi^{\langle \lambda, \sigma \cdot \alpha \rangle} \cdot c_{(\sigma \cdot \alpha)_{\lambda}}.$$

Following [63], a  $\Sigma$ -orbit in  $\Phi(\mathbf{T})$  is called *symmetric* if it is closed under  $\alpha \mapsto -\alpha$  and *anti-symmetric* otherwise. Let  $Sym(\mathbf{T})$  be a set of representatives for the symmetric  $\Sigma$ -orbits in  $\Phi(\mathbf{T})$ .

For any  $\alpha \in \Phi(\mathbf{T})$ , define

$$\Sigma_{\alpha} = \{ \tau \in \Sigma : \ \tau \cdot \alpha = \alpha \},\$$

and let  $k_{\alpha} \subset \bar{k}$  be the fixed field of the pre-image of  $\Sigma_{\alpha}$  in  $\operatorname{Gal}(\bar{k}/k)$ .

For each  $\alpha \in Sym(\mathbf{T})$ , define

$$\Sigma_{\pm\alpha} = \{ \tau \in \Sigma : \ \tau \cdot \alpha = \pm \alpha \},\$$

and let  $k_{\pm\alpha} \subset \bar{k}$  be the fixed field of the pre-image of  $\Sigma_{\pm\alpha}$  in  $\operatorname{Gal}(\bar{k}/k)$ . There is an integer  $m = m(\alpha)$  such that

$$\Sigma_{\pm\alpha} = \langle \sigma^m \rangle, \qquad \Sigma_\alpha = \langle \sigma^{2m} \rangle.$$

We have  $\sigma^m \alpha = -\alpha$ . The extension  $k_{\alpha}/k$  is unramified of degree 2m.

Moreover,  $k_{\alpha}/k_{\pm \alpha}$  is an unramified quadratic extension, hence corresponds via class-field theory to the character  $\chi_{\alpha} : k_{\pm \alpha}^{\times} \longrightarrow \{\pm 1\}$  given by

$$\chi_{\alpha}(x) = (-1)^{\nu(x)},$$

where v is the valuation on K. Using [63], Lemma 12.2.3 is equivalent to the following formula.

LEMMA 12.3.1.

$$\prod_{\alpha \in \text{Sym}(\mathbf{T})} \chi_{\alpha}(c_{\alpha_{\lambda}} \cdot c_{-\alpha_{\lambda}}) = \varepsilon(\mathbf{G}_{\lambda}, \mathbf{G}_{0}).$$

The proof requires a few steps.

LEMMA 12.3.2. There exists

$$c_{\alpha_{\lambda}} \cdot c_{-\alpha_{\lambda}} = n \cdot \varpi^{-\langle \lambda, \alpha + \sigma \cdot \alpha + \dots + \sigma^{(m-1)} \cdot \alpha \rangle},$$

where  $m = m(\alpha)$  and  $n \in k_{\pm \alpha}^{\times}$  is a norm from  $k_{\alpha}$ .

*Proof.* Applying Equation (35) repeatedly,

$$c_{(\sigma^k \cdot \alpha)_{\lambda}} = \operatorname{Frob}^k(c_{\alpha_{\lambda}}) \cdot \varpi^{-\langle \lambda, \sigma \cdot \alpha + \dots + \sigma^k \cdot \alpha \rangle},$$

for  $k \geq 1$ . Since  $\sigma^m \cdot \alpha = -\alpha$ ,

$$c_{-\alpha_{\lambda}} = \operatorname{Frob}^{m}(c_{\alpha_{\lambda}}) \cdot \overline{\omega}^{-\langle \lambda, \sigma \cdot \alpha + \dots + \sigma^{(m-1)} \cdot \alpha - \alpha \rangle}.$$

Hence

$$c_{\alpha_{\lambda}} \cdot c_{-\alpha_{\lambda}} = c_{\alpha_{\lambda}} \cdot \operatorname{Frob}^{m}(c_{\alpha_{\lambda}}) \cdot \overline{\omega}^{2\langle\lambda,\alpha\rangle} \cdot \overline{\omega}^{-\langle\lambda,\alpha+\sigma\cdot\alpha+\cdots+\sigma^{m-1}\cdot\alpha\rangle}.$$

Since  $c_{\alpha} \in k_{\alpha}$ , this proves the claim, with

$$n = c_{\alpha_{\lambda}} \cdot \operatorname{Frob}^{m}(c_{\alpha_{\lambda}}) \cdot \overline{\omega}^{2\langle \lambda, \alpha \rangle}.$$

Choose a set of positive roots  $\Phi^+(\mathbf{T}) \subset \Phi(\mathbf{T})$ , and set

$$2\rho = \sum_{\beta \in \Phi^+(\mathbf{T})} \beta.$$

LEMMA 12.3.3.

$$\sum_{\alpha \in \text{Sym}(\mathbf{T})} \langle \lambda, \alpha + \sigma \cdot \alpha + \dots + \sigma^{m(\alpha)-1} \cdot \alpha \rangle \equiv \langle \lambda, 2\rho \rangle \mod 2.$$

*Proof.* Let  $\mathcal{O}'_1, \ldots, \mathcal{O}'_p$  be a choice of one from each pair  $\{\mathcal{O}'_i, -\mathcal{O}'_i\}$  of antisymmetric  $\Sigma$ -orbits in  $\Phi(\mathbf{T})$ , and let  $\mathcal{O}_1, \ldots, \mathcal{O}_q$  be the symmetric  $\Sigma$ -orbits. For  $\alpha \in \Phi(\mathbf{T})$ , define  $|\alpha| = \alpha$  if  $\alpha \in \Phi^+(\mathbf{T})$ , and  $|\alpha| = -\alpha$  if  $-\alpha \in \Phi^+(\mathbf{T})$ . Set

$$\|\mathcal{O}'_i\| = \{ |\alpha| : \alpha \in \mathcal{O}'_i \}, \qquad \mathcal{O}^+_j = \mathcal{O}_j \cap \Phi^+(\mathbf{T}).$$

Then we have a disjoint union

$$\Phi^+(\mathbf{T}) = \prod_{i=1}^p \|\mathcal{O}'_i\| \ \sqcup \ \prod_{j=1}^q \mathcal{O}^+_j.$$

For any  $1 \leq i \leq p$ ,

$$\sum_{eta \in \|\mathcal{O}_i'\|} eta \equiv \sum_{lpha \in \mathcal{O}_i'} lpha \mod 2\mathbb{Z}\Phi(\mathbf{T}).$$

The latter sum is  $\Sigma$ -invariant, hence it vanishes, since  $\sigma$  is elliptic. Then,

$$\langle \lambda, 2\rho 
angle \equiv \sum_{j=1}^{q} \sum_{eta \in \mathcal{O}_{j}^{+}} \langle \lambda, \beta 
angle \mod 2.$$

Working modulo two, we can replace each sum over  $\mathcal{O}_j^+$  by

$$\sum_{k=0}^{m(\alpha)-1} \langle \lambda, \sigma^k \cdot \alpha \rangle,$$

for any  $\alpha \in \mathcal{O}_j$ . This proves the lemma.

Combining Lemmas 12.3.2 and 12.3.3, we get

Corollary 12.3.4.

$$\prod_{\alpha \in \text{Sym}(\mathbf{T})} \chi_{\alpha}(c_{\alpha_{\lambda}} \cdot c_{-\alpha_{\lambda}}) = (-1)^{\langle \lambda, 2\rho \rangle}.$$

We next give another expression for  $\varepsilon(\mathbf{G}_{\lambda}, \mathbf{G}_{0})$ . Let  $z_{\lambda} \in W_{o}$  be the projection of  $u_{\lambda}$ . Then  $z_{\lambda}$  and  $\vartheta$  act linearly on the  $\mathbb{Q}$ -vector space  $V := X \otimes \mathbb{Q}$  (recall that  $X = X_{*}(\mathbf{T})$ ), and the *k*-rank of  $\mathbf{G}_{\lambda}$  is given by

$$\operatorname{rk}(\mathbf{G}_{\lambda}) = \dim V^{z_{\lambda}\vartheta}$$

Let det(A) denote the determinant of an operator  $A \in GL(V)$ .

Lemma 12.3.5.

$$\varepsilon(\mathbf{G}_{\lambda}, \mathbf{G}_0) = \det(z_{\lambda}).$$

*Proof.* Since  $z_{\lambda}\vartheta$  has finite order and preserves the lattice  $X \subset V$ ,

$$\det(z_{\lambda}\vartheta) = (-1)^{\dim V - \dim V^{z_{\lambda}\vartheta}}.$$

Likewise,

$$\det(\vartheta) = (-1)^{\dim V - \dim V^\vartheta}.$$

Together, these give

$$\det(z_{\lambda}) = (-1)^{\dim V^{z_{\lambda}\vartheta} - \dim V^{\vartheta}} = \varepsilon(\mathbf{G}_{\lambda}, \mathbf{G}_{0}).$$

To prove Lemma 12.3.1 it remains to prove

LEMMA 12.3.6.

$$\det(z_{\lambda}) = (-1)^{\langle \lambda, 2\rho \rangle}.$$

870

*Proof.* From the definitions we see that  $z_{\lambda} = z_{\lambda+\nu}$  for any  $\nu \in X^{\circ} + X^W$ , where  $X^{\circ}$  is the co-root lattice of **T**. Likewise, the parity of  $\langle \lambda, 2\rho \rangle$  depends only on the class of  $\lambda$  in  $X/(X^{\circ} + X^W)$ . We have  $\det(z_{\lambda}) = (-1)^{\langle \lambda, 2\rho \rangle} = +1$  if  $\lambda \in X^{\circ} + X^W$ .

Assume now that  $\lambda \notin X^{\circ} + X^{W}$ . Recall that  $\mathbf{T}_{ad}$  is the image of  $\mathbf{T}$  in the adjoint group  $\mathbf{G}_{ad}$  of  $\mathbf{G}$ , and that  $X_{ad} = X_*(\mathbf{T}_{ad})$ . We may view  $X^{\circ}$  as a subgroup of  $X_{ad}$ . The natural map  $X \to X_{ad}$  induces an injection

$$X/(X^{\circ} + X^W) \hookrightarrow X_{\mathrm{ad}}/X^{\circ}.$$

The nontrivial elements in the group  $X_{ad}/X^{\circ}$  are represented by the minuscule co-weights of  $\mathbf{T}_{ad}$  [9, p. 240]. Hence the class of  $\lambda$  in  $X/(X^{\circ} + X^W)$  determines a simple root  $\alpha \in \Phi^+(\mathbf{T})$  such that  $\langle \lambda, \beta \rangle = 0$  for all simple roots  $\beta \neq \alpha$ , and  $\langle \lambda, \alpha \rangle = 1$ . Moreover, we have a disjoint union

$$\Phi(\mathbf{T}) = \Phi_{-1} \sqcup \Phi_0 \sqcup \Phi_1,$$

where

$$\Phi_i = \{\beta \in \Phi(\mathbf{T}) : \langle \lambda, \beta \rangle = i\}$$

(see [9, p. 239]).

Iwahori-Matsumoto [30, 1.18] show that  $z_{\lambda}$  is  $W_o$ -conjugate to the unique element of  $W_o$  whose set of positive roots made negative is exactly  $\Phi_1$ . This implies that

$$\det(z_{\lambda}) = (-1)^{|\Phi_1|}.$$

On the other hand, since

$$\Phi^+(\mathbf{T}) = [\Phi_0 \cap \Phi^+(\mathbf{T})] \sqcup \Phi_1,$$

it follows that

$$\langle \lambda, 2\rho \rangle = \sum_{\beta \in \Phi_1} \langle \lambda, \beta \rangle = |\Phi_1|$$

This proves the present lemma, as well as Lemma 12.3.1.

871

12.4. Murnaghan-Kirillov theory. In this section, **H** is any connected reductive k-group, split over K, with Frobenius F on  $H := \mathbf{H}(K)$ . Let  $H_{0^+}$ ,  $\mathfrak{h}_{0^+}$ denote respectively the sets of topologically unipotent elements in H, and topologically nilpotent elements in  $\mathfrak{h} = \text{Lie}(H)$ .

We make the following restrictions on k and  $\mathbf{H}$ . Recall that q, a power of a prime p, is the cardinality of the residue field  $\mathfrak{f}$ . Let e denote the ramification degree of k over  $\mathbb{Q}_p$ , and let  $\nu(\mathbf{H})$  be the number of positive roots in  $\mathbf{H}$ .

RESTRICTIONS 12.4.1. (1)  $q \ge \nu(\mathbf{H})$ .

(2) There is a faithful k-embedding  $\varphi : \mathbf{H} \hookrightarrow \mathrm{GL}_n$  such that  $p \ge (2+e)n$ .

Note that if **G** is as in the previous part of the paper, **H** is the identity component of the centralizer of a topological semisimple element in  $G_0$ , and Restrictions 12.4.1 hold for **G** and some n, then they hold for **H**, with the same n.

In Appendices A and B we will prove:

LEMMA 12.4.2. Assume Restrictions 12.4.1 hold. Then we have:

- For every F-stable facet J ⊆ B(H) and maximal F-stable torus S ⊂ H<sub>J</sub> with Lie algebra L<sub>S</sub>, there is an element X<sub>S</sub> ∈ L<sub>S</sub><sup>F</sup> whose centralizer in H<sub>J</sub> is exactly S.
- (2) There is an  $\langle F \rangle \ltimes H$ -equivariant bijection  $\log : H_{0^+} \longrightarrow \mathfrak{h}_{0^+}$ , which induces, for every minimal F-stable facet  $J \subseteq \mathcal{B}(H)$ , an  $\langle F \rangle \ltimes \mathsf{H}_J$ equivariant bijection from the set of unipotent elements of  $\mathsf{H}_J$  to the set of nilpotent elements of the Lie algebra of  $\mathsf{H}_J$ .

Recall that for  $S \in \mathfrak{T}(H)$  there is a unique *F*-stable facet  $J \subset \mathcal{B}(H)$  such that  $J^F = \mathcal{B}(S)^F$ , and that S denotes the image of S in  $H_J$ . Let Z denote the maximal k-split torus in the center of **H**. The following lemma is a special case of a result in [18].

LEMMA 12.4.3. Assume Restrictions 12.4.1 hold. For each  $S \in \mathfrak{T}(H)$ , with (S, J) as above, and any  $X_S \in \text{Lie}(S) \cap \mathfrak{h}_J^F$  whose projection to  $\mathsf{L}_S^F$  is an element  $\overline{X}_S$  as in 12.4.2, we have the equality

$$R(H, S, 1)(\gamma) = \varepsilon(\mathbf{H}, \mathbf{Z}) \cdot \hat{\mu}_{X_{\mathsf{S}}}^{H^{F}}(\log(\gamma)),$$

for every regular semisimple  $\gamma \in H_{0^+}^F$ , where log is as in Lemma 12.4.2.

*Proof.* Fix a regular semisimple  $\gamma \in H^F_{0^+}$ . Let  $d\ell$  denote the Haar measure on  $H^F_J$  with  $\text{meas}_{d\ell}(H^F_J) = 1$ . Now,

$$R(H, S, 1)(\gamma) = \frac{\operatorname{meas}_{dz}(Z_J^F)}{\operatorname{meas}_{dh}(H_J^F)} \cdot \int_{H^F/Z^F} dh^* \int_{H_J^F} \dot{R}_{\mathsf{S}, 1}^{\mathsf{H}_J}({}^{h\ell}\gamma) \, d\ell.$$

On the other hand, from [2, Prop. 3.3.1], we can write (36)

$$\hat{\mu}_{X_{\mathsf{S}}}^{H^{F}}(X) = \frac{\operatorname{meas}_{dz}(Z_{J}^{F})}{\operatorname{meas}_{ds}((C_{H}(X_{\mathsf{S}}))_{J}^{F})} \cdot \int_{H^{F}/Z^{F}} dh^{*} \int_{H_{J}^{F}} d\ell \int_{H_{J}^{F}} \Lambda(B(\ell'h\ell X, X_{\mathsf{S}})) d\ell'$$

where  $X = \log \gamma$  and ds is the Haar measure on  $(C_H(X_{\mathsf{S}}))^F$ , normalized as in Section 5. (Note that in [2] the quotient measure is normalized slightly differently.)

From [2, Lemma 6.1.1] we see that the inner integral in Equation (36) is zero unless  ${}^{h\ell}X \in \mathfrak{h}_{I}^{F}$ . Consequently, it is enough to show that if  ${}^{h\ell}X \in \mathfrak{h}_{I}^{F}$ , then

(37) 
$$\dot{R}_{\mathsf{S},1}^{\mathsf{H}_J}({}^{h\ell}\gamma) = \frac{\varepsilon(\mathbf{H}, \mathbf{Z}) \cdot \operatorname{meas}_{dh}(H_J^F)}{\operatorname{meas}_{ds}((C_H(X_{\mathsf{S}}))_J^F)} \cdot \int_{H_J^F} \Lambda(B({}^{\ell'h\ell}X, X_{\mathsf{S}})) \, d\ell'.$$

But since

$$\operatorname{meas}_{ds}((C_H(X_{\mathsf{S}}))_J^F) = \frac{|\mathsf{S}^F|}{|\mathsf{L}_{\mathsf{S}}^F|^{1/2}},$$

and

$$\varepsilon(\mathbf{H}, \mathbf{Z}) = \varepsilon(\mathsf{H}_J, \mathsf{S})$$

because S is minisotropic, Equation (37) follows immediately from [31, Th. 3] and the properties of the map log in Lemma 12.4.2.  $\Box$ 

12.5. Completion of the proof of stability. In this section, we prove 12.0.1, assuming that Restrictions 12.4.1 are in place.

Let  $\mathcal{T}_{st}$  be an *H*-stable class in  $\mathfrak{T}(H)$ . We fix  $S_0 \in \mathcal{T}_{st}$  and  $X_0 := X_{S_0} \in \mathfrak{h}^F$  as in 12.4.3.

LEMMA 12.5.1. The map  $X \mapsto C_G(X)$  induces a surjective map

$$c: [\mathrm{Ad}(H) \cdot X_0]^F / H^F \longrightarrow \mathcal{T}_{\mathrm{st}} / H^F,$$

whose fiber over the  $H^F$ -orbit of  $S \in T_{st}$  is in bijection with  $N(H, S^F)/SN(H^F, S)$ .

*Proof.* Note that

$$[\mathrm{Ad}(H) \cdot X_0]^F = \{ {}^h X_0 : h \in H, \text{ and } h^{-1} F(h) \in S_0 \},\$$

and recall that

$$\mathcal{T}_{st} = \{ {}^{h}S_{0} : h \in H, \text{ and } {}^{h}(S_{0}^{F}) = ({}^{h}S_{0})^{F} \}.$$

Since  $h^{-1}F(h) \in S_0$  if and only if  ${}^{h}(S_0^F) = ({}^{h}S_0)^F$ , it follows that

$$\{C_G(X): X \in [\operatorname{Ad}(H) \cdot X_0]^{F}\} = \mathcal{T}_{\operatorname{st}}.$$

One checks that for  $k, h \in H$  with  ${}^{k}X, {}^{h}X \in \mathfrak{h}^{F}$ , we have that  $C_{G}({}^{k}X)$  is  $H^{F}$ -conjugate to  $C_{G}({}^{h}X)$  if and only if there is  $\ell \in H^{F}$  such that  $k^{-1}\ell h \in N(H, S_{0}^{F})$ . It follows that the fiber of c over the  $H^{F}$ -orbit of  ${}^{k}S_{0}$  consists of the distinct  $H^{F}$ -orbits  $\operatorname{Ad}(H^{F})({}^{gn}X)$ , as n ranges over coset representatives for  $N(H, ({}^{k}S_{0})^{F})/{}^{k}S_{0}N(H^{F}, {}^{k}S_{0})$ .

LEMMA 12.5.2. If Restrictions 12.4.1 hold, then Lemma 12.0.1 holds.

Proof. Using Lemmas 12.4.3 and 12.5.1, we have

$$\begin{split} Q(H,\mathcal{T}_{\mathrm{st}})(\gamma_{\mathrm{u}}) &= \sum_{S \in \mathcal{T}_{\mathrm{st}}/H^{F}} |N(H,S^{F})/SN(H^{F},S)| \cdot R(H,S,1)(\gamma_{\mathrm{u}}) \\ &= \varepsilon(\mathbf{H},\mathbf{Z}) \cdot \sum_{S \in \mathcal{T}_{\mathrm{st}}/H^{F}} |N(H,S^{F})/SN(H^{F},S)| \cdot \hat{\mu}_{X_{S}}^{H^{F}}(\log(\gamma_{\mathrm{u}})) \\ &= \varepsilon(\mathbf{H},\mathbf{Z}) \cdot \sum_{X \in [\mathrm{Ad}(H) \cdot X_{0}]^{F}/H^{F}} \hat{\mu}_{X}^{H^{F}}(\log(\gamma_{\mathrm{u}})) \\ &= \varepsilon(\mathbf{H},\mathbf{Z}) \cdot \hat{S}_{X_{0}}^{\mathfrak{h}}(\log(\gamma_{\mathrm{u}})). \end{split}$$

A similar result holds for  $Q({}^{g}H, \iota_{g}\mathcal{T}_{st})({}^{g}\gamma_{u})$ . The result now follows from Examples 12.2.1, 12.2.2 and Lemma 12.2.3.

## 13. L-packets arising from the opposition involution

We illustrate our *L*-packets with a canonical example. For simplicity, take **G** to be absolutely quasi-simple and simply connected, and let  $w_o$  be the unique element of  $W_o$  such that  $w_o \cdot C = -C$ . Up to isomorphism, there is a unique *K*-split *k*-structure on **G** for which the Frobenius F acts on *X* by  $\vartheta = -w_o$ . This *k*-structure is quasi-split, and we have  $H^1(\mathbf{F}, G) = 1$ .

We tabulate the groups **G** below, using their names from the tables of [60], and give the number  $r := [X_{\text{ad}}^{\vartheta} : j(X^{\vartheta})]$  of generic representations in an *L*-packet  $\Pi(\varphi)$  (see Lemma 6.2.2).

G	$^{2}A'_{2m}$	$^{2}A'_{2m-1}$	$B_n$	$C_n$	$D_{2m}$	${}^{2}D_{2m+1}$	$G_2$	$F_4$	$^{2}E_{6}$	$E_7$	$E_8$
r	1	2	2	2	4	2	1	1	1	2	1

Now let  $\varphi$  be a TRSELP whose associated w is  $w_o$ . Since  $w_o \vartheta = -$  Id, the *L*-packet  $\Pi(\varphi)$  is parametrized by

$$\operatorname{Irr}(C_{\varphi}) = X/2X,$$

where  $X = X^{\circ}$  is the co-root lattice of **T** in **G**. In particular,  $|\Pi(\varphi)| = 2^n$ , where *n* is the absolute rank of **G**. With Haar measure normalized as in Section 5.3, each representation  $\pi \in \Pi(\varphi)$  has formal degree

$$Deg(\pi) = (q^{1/2} + q^{-1/2})^{-n}$$

Since  $W_o^{w_o\vartheta} = W_o$ , the full Weyl group  $W_o$  acts on  $\operatorname{Irr}(C_{\varphi})$ . This action has several interpretations.

First, by Lemma 9.6.1, the  $W_o$ -orbits on X/2X are in bijection with the  $G^{\text{F}}$ -orbits in the G-stable class  $\mathcal{T}_{w_o}$ . The tori in this stable class are k-isomorphic to  $\mathbf{U}_1^n$ .

875

Second, the  $W_o$ -orbits in X/2X are in bijection, via evaluation at -1, with conjugacy-classes of 2-torsion elements in **G** (or *G*, since **G** is simply-connected, and Lemma 2.9.1 applies). For each  $\lambda \in X$ , we have

$$x_{\lambda} = \frac{1}{2}t_{\lambda} \cdot o,$$

and the root datum, with  $F_{\lambda}$ -action, of  $G_{x_{\lambda}}$  is that of the centralizer in **G** of  $\lambda(-1)$ . The generic representations in  $\Pi(\varphi)$  correspond to the 2-torsion elements in the center of **G**.

For exceptional groups, the 2-torsion picture places a strong limitation on the type of inducing parahorics that appear in  $\Pi(\varphi)$ . For example, in  $E_8$  there are three  $W_o$ -orbits in X/2X. The *L*-packet  $\Pi(\varphi)$  has 256 = 1 + 120 + 135representations, induced from parahoric subgroups of type  $E_8$ ,  $A_1E_7$ ,  $D_8$ , respectively.

Third and finally, the generic representations in  $\Pi(\varphi)$  are parametrized by the  $W_o$ -invariants:

$$\operatorname{Irr}(C_{\varphi})_{gen} = \operatorname{Irr}(C_{\varphi})^{W_o}$$

Containment " $\subseteq$ " is shown in Remark 6.2.5. For the other containment, note that a  $W_o$ -invariant element in  $X_{\rm ad}/2X_{\rm ad}$  corresponds to a central 2-torsion element in  $\mathbf{G}_{\rm ad}$ , hence must be trivial. Containment " $\supseteq$ " now follows from Lemma 6.2.1.

#### Appendix A. Good bilinear forms and regular elements

In the appendices, we prove various results used in the proof of stability. Here **G** is any connected reductive k-group, not necessarily split over K, and F is the corresponding Frobenius automorphism of G.

A.1. Good bilinear forms. We say that a symmetric bilinear form B on  $\mathfrak{g}$  is "good" if B is  $\langle F \rangle \ltimes G$ -equivariant, nondegenerate, and restricts to the Killing form, B', on the derived algebra  $\mathfrak{g}' = [\mathfrak{g}, \mathfrak{g}]$  of  $\mathfrak{g}$ .

Let  $\mathfrak{g}_{x,t}$ ,  $\mathfrak{g}_{x,t^+}$  be the Moy-Prasad filtration subalgebras of  $\mathfrak{g}$  attached to  $x \in \mathcal{B}(G)$  and  $t \in \mathbb{R}$ . (See §B.5 below for a brief introduction to Moy-Prasad filtrations.)

LEMMA A.1.1. If p > n + 1, where  $n \ge 2$  is the dimension of a faithful k-representation of **G**, then there exists a good bilinear form B on  $\mathfrak{g}$  which induces, for all  $x \in \mathcal{B}(G)$  and for all  $t \in \mathbb{R}$ , a nondegenerate pairing

$$\mathfrak{g}_{x,t}/\mathfrak{g}_{x,t^+} imes\mathfrak{g}_{x,(-t)}/\mathfrak{g}_{x,(-t)^+} o\mathfrak{F}.$$

Remark A.1.2. If B satisfies Lemma A.1.1 and x is F-fixed, then the induced pairing,

$$\mathfrak{g}_{x,t}/\mathfrak{g}_{x,t^+} imes \mathfrak{g}_{x,(-t)}/\mathfrak{g}_{x,(-t)^+} o \mathfrak{F},$$

is  $\langle F \rangle \ltimes G_x$ -equivariant.

*Proof.* The existence of such a form B follows from the proof of [4, Prop. 4.1] under the condition that  $p \nmid B'(H_{\alpha}, H_{\alpha})$  for any root  $\alpha$  of a maximal torus  $\mathbf{T} \subset \mathbf{G}$ , where  $H_{\alpha}$  is the corresponding Chevalley basis vector in the Lie algebra of  $\mathbf{T}$ .

Let  $\mathfrak{g}_1, \ldots, \mathfrak{g}_r$  be the simple factors of  $\mathfrak{g}'$ . Let  $m_i^*$  be the sum of the coefficients in the expression of the highest co-root of  $\mathfrak{g}_i$  in terms of simple co-roots. From [54, I.4.8], any prime dividing  $B'(H_\alpha, H_\alpha)$  must divide  $6(m_i^* + 1)$ , where  $\mathfrak{g}_i$  is the factor containing  $\alpha$ .

Let  $m^* = \max\{m_i : 1 \le i \le r\}$ . We have  $n \ge m^*$ . To prove this, one may assume  $\mathfrak{g}$  simple, and check the result case-by-case (recall that k has characteristic zero). The result follows.

A.2. Regular elements. Suppose J is an F-stable facet in  $\mathcal{B}(G)$  and S is a maximal f-torus in  $\mathsf{G}_J$ . We wish to establish conditions on p and q which will guarantee that the Lie algebra  $\mathsf{L}^F_\mathsf{S}$  contains a regular semisimple element of  $\mathsf{L}_J$ .

Let  $F_0$  be the *q*-power Frobenius of  $\mathfrak{F}/\mathfrak{f}$ . Let  $\Phi_J$  be the set of  $\mathfrak{F}$ -roots of  $\mathsf{G}_J$  with respect to  $\mathsf{S}$ , and let  $\ell = \dim \mathsf{L}_{\mathsf{S}}$ . There is a permutation  $\tau$  of  $\Phi_J$  such that

$$\alpha \circ F = F_0 \circ \tau(\alpha)$$

for all  $\alpha \in \Phi_J$ . Let *d* be the order of  $\tau$ . Let  $\overline{\Phi}_J$  be the set of orbits in  $\Phi_J$  under the group generated by  $\tau$  and  $\alpha \mapsto -\alpha$ .

LEMMA A.2.1. If  $p \neq 2$  and  $q > \left| \bar{\Phi}_J \right|$ , then  $L_S^F$  contains a regular element of  $L_J$ .

Proof. Set  $\mathfrak{f}_d := \mathfrak{f}^{F_0^d}, \ \mathsf{L}^d_{\mathsf{S}} := \mathsf{L}^{F^d}_{\mathsf{S}}.$  The  $\mathfrak{f}$ -linear map  $\operatorname{tr} : \mathsf{L}^d_{\mathsf{S}} \longrightarrow \mathsf{L}^F_{\mathsf{S}},$ 

given by

$$\operatorname{tr} X := \sum_{j=0}^{d-1} F^j(X)$$

has the property that for all  $\alpha \in \Phi_J$ , the composition  $\alpha \circ \text{tr}$  is not identically zero on  $\mathsf{L}^d_{\mathsf{S}}$ . Indeed, suppose there exists  $\alpha \in \Phi_J$  for which  $\alpha \circ \text{tr}$  is zero. Since  $\mathsf{S}$  is  $\mathfrak{f}_d$ -split, we can assume that the Chevalley basis vector  $H_\alpha$  belongs to  $\mathsf{L}^d_{\mathsf{S}}$ . For all  $t \in \mathfrak{f}_d$ , we have

$$0 = \alpha(\operatorname{tr}(tH_{\alpha}))$$
  
=  $\alpha(tH_{\alpha} + t^{q}H_{\tau\alpha} + \dots + t^{q^{d-1}}H_{\tau^{d-1}\alpha})$   
=  $t\langle \alpha, \check{\alpha} \rangle + t^{q}\langle \alpha, \check{\tau\alpha} \rangle + \dots + t^{q^{d-1}}\langle \alpha, \tau^{d-1}\alpha \rangle.$ 

Since  $p \neq 2$ , we have  $\langle \alpha, \check{\alpha} \rangle \neq 0$ . Hence we have a nonzero polynomial of degree at most  $q^{d-1}$  but with  $q^d$  zeros in  $\mathfrak{F}$ , a contradiction.

Thus, for each  $\alpha \in \Phi_J$  we have a nonzero f-linear map

$$\alpha \circ \operatorname{tr} : \mathsf{L}^d_{\mathsf{S}} \longrightarrow \mathfrak{f}_d.$$

Let  $Z_{\alpha}$  be the kernel of this linear map. Since

$$F_0(\tau(\alpha)(\operatorname{tr} X)) = \alpha(\operatorname{tr} X),$$

we have  $Z_{\tau(\alpha)} = Z_{\alpha}$  and  $Z_{\alpha} = Z_{-\alpha}$ . Hence the subspace  $Z_{\alpha}$  depends only on the image of  $\alpha$  in  $\overline{\Phi}_J$ .

It suffices to show that the set

$$\mathsf{L}^{\circ}_{\mathsf{S}} := \mathsf{L}^{d}_{\mathsf{S}} \setminus \bigcup_{\alpha \in \bar{\Phi}_{J}} Z_{\alpha}$$

is nonempty. We have

$$|\mathsf{L}^{\circ}_{\mathsf{S}}| = \left|\mathsf{L}^{d}_{\mathsf{S}}\right| - \left|\bigcup_{\bar{\alpha}\in\bar{\Phi}_{J}}Z_{\alpha}\right| \ge q^{\ell d} - \left|\bar{\Phi}_{J}\right|\left|Z_{\beta}\right|,$$

where  $\beta$  is chosen so that  $|Z_{\beta}| = \max\{|Z_{\alpha}|: \alpha \in \overline{\Phi}_J\}$ . Since  $\dim_{\mathfrak{f}} Z_{\beta} \leq \ell d - 1$ , we have  $|Z_{\beta}| \leq q^{\ell d - 1}$ . Consequently,

$$|\mathsf{L}_{\mathsf{S}}^{\circ}| \ge q^{\ell d} - \left|\bar{\Phi}_{J}\right| q^{\ell d-1}.$$

Therefore  $q > |\bar{\Phi}_J|$  ensures that  $\mathsf{L}^{\circ}_{\mathsf{S}}$  is nonempty.

Note that

$$|\Phi_J| \leq \nu(\mathfrak{g})$$

where  $\nu(\mathfrak{g})$  is the number of positive (absolute) roots in  $\mathfrak{g}$ .

If p is not a torsion prime for  $G_J$ , then the centralizer in  $G_J$  of any semisimple element in  $L_J$  is connected [58, Th. 3.14]. The torsion primes of  $G_J$  are also torsion primes of G. Consequently, if p is not a torsion prime for G, then any regular element of  $L_S$  has centralizer equal to S. The torsion primes of G are less than the number  $m^*$  defined in the proof of Lemma A.1.1. Putting all this together with Lemma A.2.1 gives the following result. Let n be as in Lemma A.1.1.

LEMMA A.2.2. If p > n+1 and  $q > \nu(\mathfrak{g})$ , then for every *F*-stable facet *J* in  $\mathcal{B}(G)$ , and every maximal *F*-stable maximal torus  $S \subset G_J$ , the Lie algebra  $\mathsf{L}_{\mathsf{S}}^F$  contains an element whose centralizer in  $\mathsf{G}_J$  is exactly  $\mathsf{S}$ .

### Appendix B. A logarithm mapping for G

Let *e* denote the ramification degree of *k* over  $\mathbb{Q}_p$ , and let  $\varphi : \mathbf{G} \longrightarrow \mathbf{GL}_n$ be a faithful *k*-representation. We suppose that  $\nu(K^{\times}) = \mathbb{Z}$  where  $\nu$  is the valuation on *K*. For notational convenience we sometimes write  $(G^F)_{0^+}$  instead of  $(G_{0^+})^F$ .

The purpose of this appendix is to prove the following lemma.

LEMMA B.0.3. If  $p \ge (2+e)n$ , then there exists an  $\langle F \rangle \ltimes G$ -equivariant bijective map

$$\log\colon G_{0^+} \to \mathfrak{g}_{0^+}$$

which, for each F-stable facet J in  $\mathcal{B}(G)$ , induces a  $\langle F \rangle \ltimes \mathsf{G}_J$ -equivariant bijective map from the set of unipotent elements in  $\mathsf{G}_J$  to the set of nilpotent elements in  $\mathsf{L}_J$ .

B.1. The exponential map for the general linear group. Recall that q is the order of the residue field of k. For each  $X \in \mathfrak{gl}_n(k)$  we have  $X \in \mathfrak{gl}_n(k)_{0^+}$ if and only if  $|\mu| \leq q^{-1/n}$  for each eigenvalue  $\mu$  of X. For each  $g \in \operatorname{GL}_n(k)$ , we have  $g \in \operatorname{GL}_n(k)_{0^+}$  if and only if  $|\mu - 1| \leq q^{-1/n}$  for each eigenvalue  $\mu$  of g.

We begin with a technical result.

LEMMA B.1.1. If 
$$p > en + 1$$
, then  
(1)  $\frac{q^{-j/n}}{|j!|} \le q^{-1/n}$  for  $j \ge 2$  and  
(2)  $\frac{q^{-j/n}}{|j!|} \to 0$ .

Proof. Set

$$A(j) := \left\lfloor \frac{j}{p} \right\rfloor + \left\lfloor \frac{j}{p^2} \right\rfloor + \left\lfloor \frac{j}{p^3} \right\rfloor + \cdots$$

Note that

$$\frac{q^{-j/n}}{|j!|} = \frac{q^{-j/n}}{q^{-eA(j)}} = q^{(neA(j)-j)/n}.$$

To establish item (1) it is enough to show

$$(38) neA(j) - j \le -1,$$

and to establish item (2) it is enough to show

(39) 
$$neA(j) - j \le \frac{-j}{(p-1)}.$$

Write

$$j = \sum_{i=0}^{\ell} b_i p^i$$

with  $b_i \in \{0, 1, 2, \dots, (p-1)\}$  and  $b_\ell \neq 0$ . Now,

$$\left\lfloor \frac{j}{p^t} \right\rfloor = \sum_t^\ell b_i p^{i-t}$$

for  $1 \le t \le \ell$ . Consequently,  $(p-1)A(j) = \sum_{i=0}^{\ell} b_i(p^i-1) = j - \sum b_i$ . Thus,  $enA(j) < (p-1)A(j) \le (j-1),$  establishing (38), and

$$(p-1)(neA(j)-j) = nej - ne\sum_{i=1}^{n} b_i - (p-1)j$$
$$< (ne-p+1)j \le -j$$

establishing (39).

Our assumption  $p \ge (2+e)n$  ensures that p > en + 1. Thus, thanks to Lemma B.1.1 and [25, §10.1], the map exp defined by

$$X \mapsto \sum_{\ell=0}^{\infty} \frac{X^{\ell}}{\ell!}$$

converges to a  $\operatorname{GL}_n(k)$ -equivariant bijective analytic map from  $\mathfrak{gl}_n(k)_{0^+}$  to  $\operatorname{GL}_n(k)_{0^+}$ . We extend exp to an  $\langle F \rangle \ltimes \operatorname{GL}_n(K)$ -equivariant bijective analytic map from  $\mathfrak{gl}_n(K)_{0^+}$  to  $\operatorname{GL}_n(K)_{0^+}$  as follows. For each  $m \in \mathbb{Z}_{\geq 1}$ , by replacing k by  $K^{F^m}$  in the discussion above, we obtain an analytic map  $\exp_m : (\mathfrak{gl}_n(K)_{0^+})^{F^m} \to (\operatorname{GL}_n(K)_{0^+})^{F^m}$ . Thus, if  $X \in \mathfrak{gl}_n(K)_{0^+}$ , we may choose  $m \in \mathbb{Z}_{\geq 1}$  so that  $X \in (\mathfrak{gl}_n(K)_{0^+})^{F^m}$  and define  $\exp(X) := \exp_m(X) \in (\operatorname{GL}_n(K)_{0^+})^{F^m} \subset \operatorname{GL}_n(K)_{0^+}$ . This gives a well-defined  $\langle F \rangle \ltimes \operatorname{GL}_n(K)$ -equivariant bijective analytic map from  $\mathfrak{gl}_n(K)_{0^+}$  to  $\operatorname{GL}_n(K)_{0^+}$ .

For each facet J in  $\mathcal{B}(\mathrm{GL}_n(K))$ , the map exp takes  $\mathfrak{gl}_n(K)_J \cap \mathfrak{gl}_n(K)_{0^+}$  to  $\mathrm{GL}_n(K)_J \cap \mathrm{GL}_n(K)_{0^+}$ . Finally, the map exp also takes the Haar measure on  $\mathfrak{gl}_n(k)$  into the Haar measure on  $\mathrm{GL}_n(k)$ .

B.2. The logarithmic mapping  $\psi$ . From [9, III, §7.3, 2, Prop. 3], there is a neighborhood V of 0 in  $\mathfrak{g}^F$  and a map  $\phi: V \to G^F$  such that  $\phi(V)$  is an open subgroup of  $G^F$  and  $\phi: V \to \phi(V)$  is a k-analytic isomorphism of analytic manifolds with the property that  $\phi(mX) = \phi(X)^m$  for all  $m \in \mathbb{Z}$  and for all  $X \in V$ . From [9, III, §7.6, 6, Prop. 10], there is a neighborhood U of the identity in  $(G^F)_{0^+}$  and a unique k-analytic map  $\psi: (G^F)_{0^+} \to \mathfrak{g}^F$  such that  $\psi(U) = V, \phi \circ \psi = 1_U$ , and  $\psi(g^m) = m\psi(g)$  for all  $g \in (G^F)_{0^+}$  and all  $m \in \mathbb{Z}$ . Note that  $\psi$  is locally injective, hence injective.

Recall that the exponential map, exp, for the general linear group was defined in Section B.1. The unique map from  $\operatorname{GL}_n(k)_{0^+}$  to  $\mathfrak{gl}_n(k)$  determined (in the sense of the previous paragraph) by exp is called log. It has the usual power series expansion. Since  $p \geq (2+e)n > en+1$ , the map log:  $\mathfrak{gl}_n(k)_{0^+} \to \operatorname{GL}_n(k)_{0^+}$  is the inverse of exp:  $\operatorname{GL}_n(k)_{0^+} \to \mathfrak{gl}_n(k)_{0^+}$  (see, for example, [25, Lemma 10.1]).

From [9, III, §4.4, Cor. 2] there is a neighborhood  $V' \subset V$  in  $\mathfrak{g}^F$  such that

(40) 
$$\varphi(\phi(X)) = \exp(d\varphi(X))$$

for all  $X \in V'$  and

$$d\varphi(\psi(g)) = \log(\varphi(g))$$

for all  $g \in \phi(V')$ . Suppose  $g \in (G)_{0^+}^F$ . Choose  $m \in \mathbb{Z}_{\geq 1}$  so that  $g^{p^m} \in \phi(V')$ . Now,

$$d\varphi(\psi(g)) = p^{-m} \cdot d\varphi(\psi(g^{p^m})) = p^{-m} \cdot \log(\varphi(g^{p^m})) = \log(\varphi(g)).$$

Thus

(41) 
$$d\varphi(\psi(g)) = \log(\varphi(g))$$

for all  $g \in (G_{0^+})^F$ .

B.3. An extension of  $\psi$ . The map  $\psi$  has a unique extension, which we shall also call  $\psi$ , to an  $\langle F \rangle \ltimes G$ -equivariant map from  $G_{0^+}$  to  $\mathfrak{g}$ . Indeed, for each  $m \in \mathbb{Z}_{\geq 1}$ , by replacing k by  $K^{F^m}$  in the discussion above, we obtain a (unique)  $K^{F^m}$ -analytic map  $\psi_m \colon (G_{0^+})^{F^m} \to \mathfrak{g}^{F^m}$  for which

$$d\varphi(\psi_m(g)) = \log(\varphi(g))$$

for all  $g \in (G_{0^+})^{F^m}$ . Thus, since  $d\varphi$  is injective, for  $m' \geq m \geq 1$  we have  $\psi_{m'}(g) = \psi_m(g)$  whenever  $g \in (G_{0^+})^{F^m}$ . In particular,  $\psi_m(g) = \psi_1(g)$  whenever  $g \in (G_{0^+})^F$ . Thus, we may define  $\psi \colon G_{0^+} \to \mathfrak{g}$  by setting  $\psi(g) = \psi_m(g)$  whenever  $g \in (G_{0^+})^{F^m}$ . To see that  $\psi$  is  $\langle F \rangle \ltimes G$  - equivariant, it is enough to check that it is *F*-equivariant. Since  $d\varphi$  is injective, it is enough to check that  $d\varphi(\psi(Fg)) = d\varphi(F(\psi(g)))$  for all  $g \in G_{0^+}$ . However,

$$\begin{aligned} d\varphi(\psi(Fg)) &= \log(\varphi(Fg)) = F \log(\varphi(g)) \\ &= F d\varphi(\psi(g)) = d\varphi(F\psi(g)). \end{aligned}$$

B.4. The adjoint representation and  $\psi$ . Suppose  $Y \in \mathfrak{gl}_n(K)_{0^+}$ . Since the valuations of the eigenvalues of  $\operatorname{ad}(Y)$  are bounded (below) by those of Y, and  $p \geq (2+e)n$ , the power series for  $\exp(\operatorname{ad}(Y))$  converges in  $\operatorname{GL}(\mathfrak{gl}_n)(K)$ , and we have

(42) 
$$\exp(\operatorname{ad}(Y)) = \operatorname{Ad}(\exp(Y)).$$

Similarly, for all  $g \in \operatorname{GL}_n(K)_{0^+}$ ,

(43) 
$$\log(\operatorname{Ad}(g)) = \operatorname{ad}(\log(g)).$$

For  $h \in G_{0^+}$ , we define  $\log(\operatorname{Ad}(h)) \in \mathfrak{gl}(\mathfrak{g})(K)$  by

$$\log(\operatorname{Ad}(h)) := -\sum_{m \ge 1} \frac{(1 - \operatorname{Ad}(h))^m}{m}.$$

Thus, for all  $h \in G_{0^+}$  and  $X \in \mathfrak{g}$ ,

$$d\varphi[\mathrm{ad}(\psi(h))X] = [\mathrm{ad}(d\varphi(\psi(h)))]d\varphi(X) \qquad \text{(from Equation (41))}$$
$$= [\mathrm{ad}(\log(\varphi(h)))]d\varphi(X) \qquad \text{(from Equation (43))}$$
$$= [\log(\mathrm{Ad}(\varphi(h)))]d\varphi(X)$$
$$= d\varphi(\log(\mathrm{Ad}(h))(X)).$$

Since  $d\varphi$  is injective, we conclude that

(44) 
$$\log(\operatorname{Ad}(h))X = \operatorname{ad}(\psi(h))X$$

for all  $h \in G_{0^+}$  and  $X \in \mathfrak{g}$ .

B.5. A brief introduction to the filtrations of Moy and Prasad. We recall here what we need from the theory of Moy-Prasad filtration lattices ([44], [43]).

Let T denote the group of K-rational points of a maximally K-split torus in  $\mathbf{G}$ . Let  $\mathcal{A}$  denote the apartment in  $\mathcal{B}(G)$  corresponding to T, let  $\Phi$  denote the set of roots of G with respect to T, and let  $\Delta$  denote the set of affine roots of G with respect to T and our valuation on K. The elements of  $\Delta$  are affine functions on  $\mathcal{A}$ . For  $\delta \in \Delta$ , we let  $\dot{\delta} \in \Phi$  denote the gradient of  $\delta$ .

For  $\alpha \in \Phi$ , let  $\mathfrak{g}_{\alpha}$  denote the corresponding root space in  $\mathfrak{g}$ . For  $\delta \in \Delta$ , define the lattices  $\mathfrak{g}_{\delta}^+$  and  $\mathfrak{g}_{\delta}$  in  $\mathfrak{g}_{\delta}$  as follows: Choose a facet J in  $\mathcal{A}$  on which  $\delta$  is zero. Set

$$\mathfrak{g}_{\delta} := \mathfrak{g}_J \cap \mathfrak{g}_{\dot{\delta}} \text{ and } \mathfrak{g}_{\delta}^+ := \mathfrak{g}_J^+ \cap \mathfrak{g}_{\dot{\delta}}.$$

These definitions are independent of the choice of J.

Since **G** is *K*-quasi-split, the centralizer  $M := C_G(T)$  is the group of *K*-rational points of a maximal *K*-torus **M** of **G**. Let  $\mathfrak{m}$  denote the Lie algebra of *M*. For  $s \in \mathbb{R}$ , we define

$$\mathfrak{m}_s := \{ X \in \mathfrak{m} \, | \, \nu(d\chi(X)) \ge s \text{ for all } \chi \in \mathbf{X}^*(\mathbf{M}) \}.$$

For  $x \in \mathcal{A}$  and  $s \in \mathbb{R}$ , we define the lattice

$$\mathfrak{g}_{x,s}:=\mathfrak{m}_s\oplus\sum_{\delta\in\Delta;\,\delta(x)\geq s}\mathfrak{g}_{\delta}.$$

For  $t \geq s$  we have  $\mathfrak{g}_{x,t} \subset \mathfrak{g}_{x,s}$ ; in fact,

$$\bigcup \mathfrak{g}_{x,s} = \mathfrak{g}, \text{ and } \bigcap_{s} \mathfrak{g}_{x,s} = \{0\}$$

We set

$$\mathfrak{g}_{x,s^+} := \bigcup_{t>s} \mathfrak{g}_{x,t}.$$

If y is in  $\mathcal{B}(G)$ , then there is a g in G so that  $gy \in \mathcal{A}$ . For  $s \in \mathbb{R}$ , we define

$$\mathfrak{g}_{y,s} := {}^g \mathfrak{g}_{x,s}$$
 and  $\mathfrak{g}_{y,s^+} := {}^g \mathfrak{g}_{x,s^+}$ .

This is independent of the choice of g.

Recall [3, §3] that, for  $s \in \mathbb{R}$ , we have the closed, open, G-invariant subsets

$$\mathfrak{g}_s := \bigcup_{x \in \mathcal{B}(G)} \mathfrak{g}_{x,s} \text{ and } \mathfrak{g}_{s^+} := \bigcup_{t>s} \mathfrak{g}_t.$$

For each  $s \in \mathbb{R}_{\geq 0}$  and each  $x \in \mathcal{B}(G)$ , we also define, in a completely analogous manner, Moy-Prasad filtration subgroups  $G_{x,s} \leq G_{x,0} = G_x$  (see [43]). The Moy-Prasad filtration lattices and subgroups have the following properties (which we shall use without further comment). The first two properties are proved in [45, §2]; the third is a formal consequence of the definitions, and the final is [1, Prop. 1.4.3].

- (1) For  $s, t \in \mathbb{R}$  and  $x \in \mathcal{B}(G)$ , we have  $[\mathfrak{g}_{x,t}, \mathfrak{g}_{x,s}] \subset \mathfrak{g}_{x,(t+s)}$ .
- (2) For  $s, t \in \mathbb{R}_{\geq 0}$  and  $x \in \mathcal{B}(G)$ , we have  $(G_{x,s}, G_{x,t}) \subset G_{x,(t+s)}$ .
- (3) For  $s \in \mathbb{R}$  and  $x \in \mathcal{B}(G)$  we have

$$\varpi \cdot \mathfrak{g}_{x,s} = \mathfrak{g}_{x,(s+1)}.$$

(4) For  $t \in \mathbb{R}_{\geq 0}$ ,  $s \in \mathbb{R}$ , and  $x \in \mathcal{B}(G)$ , we have  $(\operatorname{Ad}(g) - 1)\mathfrak{g}_{x,s} \subset \mathfrak{g}_{x,s+t}$  for all  $g \in G_{x,t}$ .

B.5.1. A technical result. The purpose of this section is to establish a (weak) connection between the Moy-Prasad filtrations for  $\mathfrak{g}$  and those for  $\mathfrak{gl}_n(K)$ . We do this so as to avoid introducing another constant ( $r_G$  below) into our hypotheses.

Fix a facet  $J \subset \mathcal{B}(G)$ . Define a continuous, piecewise-linear function  $r: J \to \mathbb{R}_{>0}$  by sending  $x \in J$  to the unique real number r(x) for which

$$\mathfrak{g}_J^+ = \mathfrak{g}_{x,r(x)} \neq \mathfrak{g}_{x,r(x)^+}$$

After extending by zero, the function r becomes a continuous function on the closure of J. Hence, we may choose  $x_J \in J$  so that

$$r(x_J) \ge r(x)$$

for all x in the closure of J. Define  $r_J := r(x_J)$ . The (rational) number  $r_J$  depends only on the G-conjugacy class of J. We set

$$r_G := \min_J r_J.$$

Note that, if J is F-stable, then, from the concavity of r and the Bruhat-Tits fixed-point theorem (see, for example, [60, §2.3.1]), we may assume that  $x_J$  is F-fixed.

LEMMA B.5.1. If C is an alcove in  $\mathcal{B}(G)$ , then  $r_G = r_C$ .

*Proof.* Without loss of generality,  $\mathbf{G}$  is semisimple. We can write

$$\mathcal{B}(G) = \prod_{i=1}^{m} \mathcal{B}(G_i)$$

where the  $\mathbf{G}_i$  are the simple factors of  $\mathbf{G}$ . This decomposition respects the polysimplicial structure of  $\mathcal{B}(G)$ . If, with respect to this decomposition,  $x \in J$  is written as

$$(x_1,\ldots,x_m),$$

then, from the way in which the Moy-Prasad filtration lattices are defined,

$$r(x) = \min\{r_1(x_1), \dots, r_m(x_m)\}.$$

Here  $r_1, \ldots, r_m$  are the analogues of  $r: J \to \mathbb{R}$ . Hence, we may in fact assume that **G** is simple.

Let J be a facet in  $\mathcal{B}(G)$  and let C be an alcove in  $\mathcal{B}(G)$ . We shall show that  $r_J \geq r_C$ . After conjugating, we may assume that J is contained in the boundary of C and that  $C \subset \mathcal{A}$ . Let  $\Delta_C$  denote the set of simple affine roots in  $\Delta$  determined by C. Let  $\Delta_J$  be the set

$$\{\delta \in \Delta_C \mid \operatorname{res}_J \delta \neq 0\} = \{\delta \in \Delta_C \mid \operatorname{res}_J \delta > 0\}.$$

We set

$$r'_J := \max_{x \in J} \min_{\delta \in \Delta_J} \delta(x),$$

and we let s denote the smallest positive number for which  $\mathfrak{m}_s \neq \mathfrak{m}_{s^+}$ . From the way in which the Moy-Prasad filtration lattices are defined, we have

$$r_J = \min\{s, r'_J\}$$
 and  $r_C = \min\{s, r'_C\}$ .

Thus, it is enough to show that  $r'_C \leq r'_J$ .

One can show that

$$r'_J = ig[\prod_{\delta \in \Delta_J} r_\deltaig] / ig[\sum_{\delta' \in \Delta_J} ig(\prod_{\delta \in \Delta_J \smallsetminus \{\delta'\}} r_\deltaig)ig]$$

where  $r_{\delta}$  denotes the maximum value that  $\delta$  obtains on the closure of J (and hence, on the closure of C).

Suppose J' is a facet in the closure of C such that J is contained in the closure of J' and  $\dim(J') = \dim(J) + 1$ . Let  $\tilde{\delta} \in \Delta_C$  denote the affine root for which  $\Delta_{J'} = \Delta_J \cup \{\tilde{\delta}\}$ . Algebraic manipulation yields

$$r'_{J'} = \frac{r_{\tilde{\delta}}}{r_{\tilde{\delta}} + r'_J} \cdot r'_J < r'_J.$$

By iterating the above process, we conclude that  $r'_C \leq r'_I$ .

Remark B.5.2. If G is simple modulo its center and K-split, then

$$r_G = (1 + \sum m_\alpha)^{-1},$$

where  $m_{\alpha}$  runs over the coefficients of the simple roots in the expression for the highest root. In particular, for  $G = \operatorname{GL}_n(K)$ , we have  $r_G = n^{-1}$ .

Lemma B.5.3.

$$\mathfrak{g}_{0^+} = \mathfrak{g}_{r_G} \neq \mathfrak{g}_{r_G^+}.$$

*Proof.* Let C be an alcove in  $\mathcal{B}(G)$ . For all J in the closure of C we have  $\mathfrak{g}_{J}^{+} \subset \mathfrak{g}_{C}^{+}$ . Consequently

$$\mathfrak{g}_{0^+} = \bigcup_{g \in G} {}^g \mathfrak{g}_C^+.$$

Thus, the equality follows from the fact that  $\mathfrak{g}_C^+ = \mathfrak{g}_{x_C,r_G}$ .

As in the proof of Lemma B.5.1, we may assume that  $\mathbf{G}$  is simple; we use the notation of that proof.

Suppose  $\mathfrak{g}_{r_G} = \mathfrak{g}_{r_G^+}$ . Under this assumption, from [3, Cor. 3.2.2] we have  $\mathfrak{g}_{x_C,r_G} \subset \mathfrak{g}_{x_C,r_G^+} + \mathcal{N}$ . Thus, from, for example, [17, §4.1.2] or [43, Prop. 4.3], every coset  $\Xi$  in  $\mathfrak{g}_{x_C,r_G^+}/\mathfrak{g}_{x_C,r_G^+}$  is killed by a one-parameter subgroup of  $\mathsf{M} := M_0/M_0^+$ ; that is, for each  $\Xi$  there exists a one-parameter subgroup  $\mu = \mu_{\Xi}$  of the f-group  $\mathsf{M}$  so that  $\lim_{t\to 0} \mu^{(t)}\Xi = 0$ . Consequently, in order to show that  $\mathfrak{g}_{r_G} \neq \mathfrak{g}_{r_G^+}$ , it is enough to find an  $X \in \mathfrak{g}_{x_C,r_G}$  for which the coset  $\Xi_X := X + \mathfrak{g}_{x_C,r_G^+}$  is not killed by any one-parameter subgroup of  $\mathsf{M}$ .

If  $s < r'_C$ , then choose  $X \in \mathfrak{m}_s \setminus \mathfrak{m}_{s^+}$ . Since M is abelian, no oneparameter subgroup of  $\mathsf{M}$  can kill  $\Xi_X$ . If  $s \ge r'_C$ , then for each  $\delta \in \Delta_C$ , we may choose  $X_{\delta}$  in the root space corresponding to the gradient of  $\delta$  so that  $X_{\delta} \in \mathfrak{g}_{x_C,r_G}$  yet  $X_{\delta} \notin \mathfrak{g}_{x_C,r_G^+}$ . From, for example, [13, Prop. 1.2], the coset  $\Xi_X$  for

$$X := \sum_{\delta} X_{\delta}$$

cannot be killed by a one-parameter subgroup of M.

LEMMA B.5.4. We have  $r_G \ge n^{-1}$ . In particular,  $G_C^+ = G_{x_C,1/n}$  and  $\mathfrak{g}_C^+ = \mathfrak{g}_{x_C,1/n}$ .

*Proof.* Since we are assuming that  $p \ge (2 + e)n$ , it follows that every K-torus in **G** or  $\operatorname{GL}_n$  splits over a tame extension of K. Hence, from the discussion in [3, §3.6] we have

$$\mathfrak{g} \cap \mathfrak{gl}_n(K)_{s^+} = \mathfrak{g}_{s^+}$$

and

$$\mathfrak{g} \cap \mathfrak{gl}_n(K)_s = \mathfrak{g}_s$$

for all s. From Remark B.5.2 and Lemma B.5.3, we have  $\mathfrak{gl}_n(K)_{0^+} = \mathfrak{gl}_n(K)_{1/n} \neq \mathfrak{gl}_n(K)_{1/n^+}$ . We conclude that  $1/n \leq r_G$ . For the last assertion, note that  $G_{x_C,r} = G_{x_C,0^+}$  for  $0 < r \leq r_G$ , and likewise for  $\mathfrak{g}_{x_C,r}$ .

B.6. A logarithmic map for semisimple groups. Suppose that  $\mathbf{G}$  is semisimple.

Moy-Prasad filtrations and the adjoint representation.

885

LEMMA B.6.1. Suppose  $x \in \mathcal{B}(G), t \in \mathbb{R}$ , and  $X \in \mathfrak{g}_{x,t}$ . Now,

$$X \not\in \mathfrak{g}_{x,t^+}$$

if and only if there exist  $q \in \mathbb{R}$  and  $Q \in \mathfrak{g}_{x,q} \setminus \mathfrak{g}_{x,q^+}$  such that

$$\operatorname{ad}(X)Q \in \mathfrak{g}_{x,(t+q)} \smallsetminus \mathfrak{g}_{x,(t+q)^+}.$$

*Proof.* " $\Leftarrow$ ": Suppose  $X \in \mathfrak{g}_{x,t^+}$ . Then for all  $q \in \mathbb{R}$  and for all  $Q \in \mathfrak{g}_{x,q}$  we have

$$\operatorname{ad}(X)Q \in \mathfrak{g}_{x,(t+q)^+},$$

a contradiction.

" $\Rightarrow$ ": From Lemma A.1.1, there exists  $Y \in \mathfrak{g}_{x,-t} \smallsetminus \mathfrak{g}_{x,(-t)^+}$  such that

 $(45) B(X,Y) \in R^{\times}.$ 

For all  $s \in \mathbb{R}$  we have

$$(\mathrm{ad}(X) \mathrm{ad}(Y))\mathfrak{g}_{x,s} \subset \mathfrak{g}_{x,s}.$$

Since **G** is semisimple, we have that *B* is the Killing form. We conclude from Equation (45) that there exist a  $q \in \mathbb{R}$  and a  $Z \in \mathfrak{g}_{x,(t+q)} \setminus \mathfrak{g}_{x,(t+q)^+}$  such that

$$\operatorname{ad}(X)(\operatorname{ad}(Y)Z) \in \mathfrak{g}_{x,(t+q)} \smallsetminus \mathfrak{g}_{x,(t+q)^+}.$$

Let  $Q := \operatorname{ad}(Y)Z \in \mathfrak{g}_{x,q}$ . Since  $\operatorname{ad}(X)Q \in \mathfrak{g}_{x,(t+q)} \setminus \mathfrak{g}_{x,(t+q)^+}$ , we conclude that  $Q \in \mathfrak{g}_{x,q} \setminus \mathfrak{g}_{x,q^+}$ .  $\Box$ 

COROLLARY B.6.2. Suppose  $x \in \mathcal{B}(G)$ ,  $s \in \mathbb{R}$ , and  $X \in \mathfrak{g}$ . Now,

$$X \in \mathfrak{g}_{x,s}$$

if and only if for all  $q \in \mathbb{R}$  and for all  $Q \in \mathfrak{g}_{x,q}$ ,

$$\operatorname{ad}(X)Q \in \mathfrak{g}_{x,(s+q)}.$$

*Proof.* " $\Rightarrow$ ": There is nothing to prove.

" $\Leftarrow$ ": If  $X \notin \mathfrak{g}_{x,s}$ , then there exists t < s such that  $X \in \mathfrak{g}_{x,t} \setminus \mathfrak{g}_{x,t^+}$ . From Lemma B.6.1, as  $X \notin \mathfrak{g}_{x,t^+}$ , there exist  $q \in \mathbb{R}$  and  $Q \in \mathfrak{g}_{x,q}$  such that  $\operatorname{ad}(X)Q \notin \mathfrak{g}_{x,(t+q)^+}$ . But  $\mathfrak{g}_{x,(s+q)} \subset \mathfrak{g}_{x,(t+q)^+}$ , so that  $\operatorname{ad}(X)Q \notin \mathfrak{g}_{x,(s+q)}$ .

Moy-Prasad filtrations and  $\psi$ , I.

Remark B.6.3. Since  $p \ge (2+e) \cdot n$ , we have  $m \ge n \cdot \nu(m) + 2$  for  $m \ge 2$ . If we assume that  $m \ge (2n-1)$ , then  $m \ge n \cdot (2+\nu(m)) - 1$ .

LEMMA B.6.4. Suppose  $x \in \mathcal{B}(G)$  and  $t \in \mathbb{R}_{\geq 1/n}$ . If  $g \in G_{x,t}$ , then for all  $q \in \mathbb{R}$  and for all  $Q \in \mathfrak{g}_{x,q}$ 

$$\log(\operatorname{Ad}(g))Q \equiv (\operatorname{Ad}(g) - 1)Q \mod \mathfrak{g}_{x,(2t+q)}.$$

Proof. Fix 
$$q \in \mathbb{R}$$
 and  $Q \in \mathfrak{g}_{x,q}$ . For  $m > 1$ ,  
$$\frac{(1 - \operatorname{Ad}(g))^m}{m}Q$$

belongs to

$$\frac{1}{m} \cdot \mathfrak{g}_{x,(q+tm)} \subset \mathfrak{g}_{x,(q+tm-\nu(m))} \\ \subset \mathfrak{g}_{x,(q+2t+t(m-2)-\nu(m))}$$

From Remark B.6.3 we have  $m \ge n \cdot \nu(m) + 2$ . Thus

$$\mathfrak{g}_{x,(q+2t+t(m-2)-\nu(m))} \subset \mathfrak{g}_{x,(q+2t)}.$$

Consequently,

$$\log(\operatorname{Ad}(g))Q \equiv (\operatorname{Ad}(g) - 1)Q \mod \mathfrak{g}_{x,(q+2t)}.$$

COROLLARY B.6.5. For all  $x \in \mathcal{B}(G)$  and for all  $s \geq 1/n$ ,

$$\psi(G_{x,s}) \subset \mathfrak{g}_{x,s}.$$

*Proof.* From Corollary B.6.2, it is enough to show that for all  $q \in \mathbb{R}$ , for all  $Q \in \mathfrak{g}_{x,q}$ , and for all  $g \in G_{x,s}$ ,

$$\operatorname{ad}(\psi(g))Q \in \mathfrak{g}_{x,(s+q)}.$$

However, from Equation (44),

$$\operatorname{ad}(\psi(g))Q = \log(\operatorname{Ad}(g))Q,$$

and  $\log(\operatorname{Ad}(g))Q \in \mathfrak{g}_{x,(s+q)}$  from Lemma B.6.4.

Logarithmic behavior of  $\psi$ .

LEMMA B.6.6. Suppose  $x \in \mathcal{B}(G)$  and  $s, t \in \mathbb{R}_{>0}$  with  $s \leq t$ . If  $g \in G_{x,s}$ and  $h \in G_{x,t}$ , then for all  $q \in \mathbb{R}$  and for all  $Q \in \mathfrak{g}_{x,q}$ ,

$$(1 - \operatorname{Ad}(gh))^m Q \equiv (1 - \operatorname{Ad}(g))^m Q \mod \mathfrak{g}_{x,(t+q+(m-1)s)}$$

for all  $m \in \mathbb{Z}_{\geq 1}$ .

*Proof.* We will argue by induction on m. Suppose  $x \in \mathcal{B}(G)$ ,  $s, t \in \mathbb{R}_{>0}$ with  $s \leq t, g \in G_{x,s}$ , and  $h \in G_{x,t}$ . For  $q \in \mathbb{R}$  and  $Q \in \mathfrak{g}_{x,q}$ , we define  $T = T(Q,h) \in \mathfrak{g}_{x,(q+t)}$  by  $T := {}^{h}Q - Q$ .

When m = 1, we have that for all  $q \in \mathbb{R}$  and for all  $Q \in \mathfrak{g}_{x,q}$ 

$$(1 - \operatorname{Ad}(gh))Q = Q - {}^{gh}Q = Q - {}^{g}Q - {}^{g}T$$
$$\equiv Q - {}^{g}Q \mod \mathfrak{g}_{x,(q+t)} = (1 - \operatorname{Ad}(g))Q.$$

886

If

$$(1 - \operatorname{Ad}(gh))^m Q' \equiv (1 - \operatorname{Ad}(g))^m Q' \text{ modulo } \mathfrak{g}_{x,(q'+t+(m-1)s)}$$
  
for all  $q' \in \mathbb{R}$  and for all  $Q' \in \mathfrak{g}_{x,q'}$ , then for all  $q \in \mathbb{R}$  and for all  $Q \in \mathfrak{g}_{x,q}$ 

$$(1 - \operatorname{Ad}(gh))^{(m+1)}Q = (1 - \operatorname{Ad}(gh))^m [(1 - \operatorname{Ad}(gh))Q]$$
(since  $s \le t$ , we have  $(1 - \operatorname{Ad}(gh))Q \in \mathfrak{g}_{x,(q+s)})$ 

$$\equiv (1 - \operatorname{Ad}(g))^m [(1 - \operatorname{Ad}(gh))Q] \mod \mathfrak{g}_{x,(q+s+t+(m-1)s)}$$
( $\equiv (1 - \operatorname{Ad}(g))^m [(1 - \operatorname{Ad}(gh))Q] \mod \mathfrak{g}_{x,(q+t+ms)})$ 

$$= [(1 - \operatorname{Ad}(g))^{(m+1)}Q] - [(1 - \operatorname{Ad}(g))^m ({}^gT)]$$
(since  ${}^gT \in \mathfrak{g}_{x,(t+q)}$  and  $s \le t$ )
$$\equiv (1 - \operatorname{Ad}(g))^{(m+1)}Q \mod \mathfrak{g}_{x,(t+q+ms)}.$$

LEMMA B.6.7. Suppose  $x \in \mathcal{B}(G)$  and  $s, t \in \mathbb{R}$  with  $t \geq s \geq 1/n$ . For all  $g \in G_{x,s}$  and for all  $h \in G_{x,t}$ ,

$$\psi(gh) \equiv \psi(g) + \psi(h) \mod \mathfrak{g}_{x,(s+t)}.$$

*Proof.* Suppose x, s, t, g, and h are as in the statement of the lemma. From Corollary B.6.2, it will be enough to show that if  $q \in \mathbb{R}$  and  $Q \in \mathfrak{g}_{x,q}$ , then

$$\operatorname{ad}[\psi(gh) - \psi(g) - \psi(h)]Q \in \mathfrak{g}_{x,(q+s+t)}.$$

Thus, from Equation (44), it will be enough to show that

$$[\log(\mathrm{Ad}(gh)) - \log(\mathrm{Ad}(g)) - \log(\mathrm{Ad}(h))]Q \in \mathfrak{g}_{x,(q+s+t)}.$$

Since

$$\frac{(1-\operatorname{Ad}(gh))^m}{m}, \ \frac{(1-\operatorname{Ad}(g))^m}{m}, \ \text{and} \ \frac{(1-\operatorname{Ad}(h))^m}{m}$$

all tend to zero in  $\mathfrak{gl}(\mathfrak{g})(K)$ , there exists  $N \in \mathbb{Z}_{>1}$ , independent of q and Q, so that

$$[\log(\mathrm{Ad}(gh)) - \log(\mathrm{Ad}(g)) - \log(\mathrm{Ad}(h))]Q$$

is equivalent to

$$-\sum_{1}^{N} \frac{1}{m} \cdot [(1 - \mathrm{Ad}(gh))^{m} - (1 - \mathrm{Ad}(g))^{m} - (1 - \mathrm{Ad}(h))^{m}]Q$$

modulo  $\mathfrak{g}_{x,(s+t+q)}$ . Fix  $2 \leq m \leq N$ . From Lemma B.6.6 we have

$$\begin{split} [(1 - \operatorname{Ad}(gh))^m - (1 - \operatorname{Ad}(g))^m - (1 - \operatorname{Ad}(h))^m]Q \\ &\equiv -(1 - \operatorname{Ad}(h))^m Q \text{ modulo } \mathfrak{g}_{x,(t+q+s(m-1))} \\ & (\text{since } t \ge s) \\ &\equiv 0 \text{ modulo } \mathfrak{g}_{x,(t+q+s(m-1))}. \end{split}$$

Thanks to Remark B.6.3, for  $m \ge 2$ ,

$$s(m-2) - \nu(m) \ge \frac{1}{n}(m-2) - \nu(m) \ge 0.$$

We conclude that for  $m \geq 2$ 

$$\frac{1}{m} [(1 - \mathrm{Ad}(gh))^m - (1 - \mathrm{Ad}(g))^m - (1 - \mathrm{Ad}(h))^m]Q$$

belongs to  $\mathfrak{g}_{x,(q+t+s)}$ . Consequently,

$$[\log(\mathrm{Ad}(gh)) - \log(\mathrm{Ad}(g)) - \log(\mathrm{Ad}(h))]Q$$

is equivalent to

$$-[(1 - \mathrm{Ad}(gh)) - (1 - \mathrm{Ad}(g)) - (1 - \mathrm{Ad}(h))]Q$$

modulo  $\mathfrak{g}_{x,(q+t+s)}$ . But the latter is  $(\operatorname{Ad}(g) - 1)(\operatorname{Ad}(h) - 1)Q$ , which belongs to  $\mathfrak{g}_{x,(q+t+s)}$ .

Remark B.6.8. The condition  $t \ge s$  in Lemma B.6.7 is not required. Suppose x, g, h are as in the statement of the lemma and  $1/n \le t < s$ . Choose  $u \in G_{x,(s+t)}$  so that  ${}^{g}h = hu$ . Then

$$\begin{split} \psi(gh) &= \psi(({}^{g}h)g) \equiv \psi({}^{g}h) + \psi(g) \mod \mathfrak{g}_{x,(s+t)} \\ &= \psi(hu) + \psi(g) \equiv \psi(h) + \psi(u) + \psi(g) \mod \mathfrak{g}_{x,(2t+s)} \\ & \text{(from Corollary B.6.5)} \\ &\equiv \psi(h) + \psi(g) \mod \mathfrak{g}_{x,(s+t)} = \psi(g) + \psi(h). \end{split}$$

We can now reformulate Lemma B.6.7 as follows.

COROLLARY B.6.9. Suppose  $x \in \mathcal{B}(G)$  and  $s, t \in \mathbb{R}_{\geq 1/n}$ . For all  $g \in G_{x,s}$ and for all  $h \in G_{x,t}$ ,

$$\psi(gh) \equiv \psi(g) + \psi(h) \mod \mathfrak{g}_{x,(s+t)}.$$

Filtration quotients and  $\psi$ .

Remark B.6.10. Since every torus of **G** splits over a tamely ramified extension of K, for all  $t \in \mathbb{R}_{>0}$  and for all  $x \in \mathcal{B}(G)$  we have an isomorphism of abelian groups

$$G_{x,t}/G_{x,t^+} \cong \mathfrak{g}_{x,t}/\mathfrak{g}_{x,t^+}.$$

This isomorphism has the property that for each coset  $\Xi_G$  in  $G_{x,t}/G_{x,t^+}$  the isomorphism identifies a coset  $\Xi_{\mathfrak{g}}$  in  $\mathfrak{g}_{x,t}/\mathfrak{g}_{x,t^+}$  so that for all  $q \in \mathbb{R}$  and for each  $Q \in \mathfrak{g}_{x,q}$  we have

$$\operatorname{ad}(X)Q \equiv (\operatorname{Ad}(g) - 1)Q \mod \mathfrak{g}_{x,(t+q)^+}$$

for all  $X \in \Xi_{\mathfrak{g}}$  and for all  $g \in \Xi_G$ . See [64, Cor. 2.4] or [65] for details.

889

LEMMA B.6.11. Suppose  $x \in \mathcal{B}(G)$  and  $t \in \mathbb{R}_{>0}$ . If  $g \in G_{x,t} \setminus G_{x,t^+}$ , then there exist  $q \in \mathbb{R}$  and  $Q \in \mathfrak{g}_{x,q} \setminus \mathfrak{g}_{x,q^+}$  such that

$$(\operatorname{Ad}(g)-1)Q \in \mathfrak{g}_{x,(t+q)} \smallsetminus \mathfrak{g}_{x,(t+q)^+}.$$

*Proof.* Choose g as in the statement of the lemma. If  $X \in \Xi_{\mathfrak{g}}$ , where  $\Xi_{\mathfrak{g}} \in \mathfrak{g}_{x,t}/\mathfrak{g}_{x,t^+}$  corresponds to the coset  $gG_{x,t^+}$  in  $G_{x,t}/G_{x,t^+}$ , then  $X \in \mathfrak{g}_{x,t} \setminus \mathfrak{g}_{x,t^+}$ . From Lemma B.6.1 we can choose  $q \in \mathbb{R}$  and  $Q \in \mathfrak{g}_{x,q} \setminus \mathfrak{g}_{x,q^+}$  so that

$$\operatorname{ad}(X)Q \in \mathfrak{g}_{x,(t+q)} \smallsetminus \mathfrak{g}_{x,(t+q)^+}.$$

Since, from Remark B.6.10,

$$(\operatorname{Ad}(g) - 1)Q \equiv \operatorname{ad}(X)Q \mod \mathfrak{g}_{x,(t+q)^+},$$

the lemma follows.

LEMMA B.6.12. Suppose  $t \ge 1/n$  and  $x \in \mathcal{B}(G)$ . The restriction of  $\psi$  to  $G_{x,t}$  induces an isomorphism

$$G_{x,t}/G_{x,t^+} \cong \mathfrak{g}_{x,t}/\mathfrak{g}_{x,t^+}$$

of abelian groups.

*Proof.* Fix  $t \geq 1/n$  and  $x \in \mathcal{B}(G)$ . Since  $\psi: G_{0^+} \to \mathfrak{g}$  is injective and from Corollary B.6.5

$$\psi(G_{x,t^+}) \subset \mathfrak{g}_{x,t^+}$$

while

$$\psi(G_{x,t}) \subset \mathfrak{g}_{x,t},$$

from Lemma B.6.7 we have that  $\psi$  induces a group homomorphism

$$G_{x,t}/G_{x,t^+} \to \mathfrak{g}_{x,t}/\mathfrak{g}_{x,t^+}.$$

We will show that this map is surjective. Since  $G_{x,t}/G_{x,t^+}$  and  $\mathfrak{g}_{x,t}/\mathfrak{g}_{x,t^+}$  are finite-dimensional  $\mathfrak{F}$ -vector spaces of the same dimension, injectivity will follow. Now, we must show that for each  $X \in \mathfrak{g}_{x,t}$  there is a  $g \in G_{x,t}$  for which

$$X - \psi(g) \in \mathfrak{g}_{x,t^+}.$$

Equivalently, from Corollary B.6.2, we need that for all  $q \in \mathbb{R}$  and for all  $Q \in \mathfrak{g}_{x,q}$ 

$$[\mathrm{ad}(X) - \mathrm{ad}(\psi(g))]Q \in \mathfrak{g}_{x,(q+t)^+}.$$

Suppose  $X \in \mathfrak{g}_{x,t}$ . From Remark B.6.10, there is a  $g \in G_{x,t}$  so that for all  $q \in \mathbb{R}$  and each  $Q \in \mathfrak{g}_{x,q}$  we have

(46) 
$$(\operatorname{Ad}(g) - 1)Q \equiv \operatorname{ad}(X)Q \mod \mathfrak{g}_{x,(q+t)^+}.$$

Now, for all  $q \in \mathbb{R}$  and for all  $Q \in \mathfrak{g}_{x,q}$ ,

$$\begin{split} [\operatorname{ad}(X) - \operatorname{ad}(\psi(g))]Q &= [\operatorname{ad}(X) - \log(\operatorname{Ad}(g))]Q & (\text{from Corollary B.6.4}) \\ &\equiv [\operatorname{ad}(X) - (\operatorname{Ad}(g) - 1)]Q \mod \mathfrak{g}_{x,(q+2t)} \\ & (\text{from Equation (46)}) \\ &\equiv 0 \mod \mathfrak{g}_{x,(q+t)^+}. \end{split}$$

Thus  $[\operatorname{ad}(X) - \operatorname{ad}(\psi(g))]Q \in \mathfrak{g}_{x,(q+t)^+}$ .

Moy-Prasad filtrations and  $\psi$ , II. We begin with an abstract result about maps between complete topological groups.

LEMMA B.6.13. Suppose H and L are complete topological groups. Let  $f: H \to L$  be a map for which there exist neighborhood bases at the identity

$$\{H_i \le H \mid H_1 := H \ge H_2 \ge H_3 \ge \dots \ge \{1\}\}$$

and

$$\{L_i \le L \mid L_1 := L \ge L_2 \ge L_3 \ge \dots \ge \{1\}\}$$

for H and L so that

- (1)  $f(H_i) \subset L_i$  for all i and
- (2) if  $h \in H_i$  and  $h' \in H_j$ , then  $f(hh') \equiv f(h)f(h')$  modulo  $L_{i+j}$ .

*If the induced map* 

$$H_i/H_{(i+1)} \to L_i/L_{(i+1)},$$

is surjective for all i, then f is surjective.

Remark B.6.14. Note that the first condition on f implies that it is continuous at the identity, while the second implies that f is continuous everywhere.

*Proof.* Suppose  $\ell \in L$ . Fix  $j_0 \in \mathbb{Z}_{\geq 1}$  so that  $\ell \in L_{j_0} \setminus L_{(j_0+1)}$ . By hypothesis, there is an  $h_0 \in H_{j_0}$  such that  $f(h_0) \equiv \ell$  modulo  $L_{(j_0+1)}$ . Fix  $j_1 > j_0$  so that  $f(h_0)^{-1}\ell \in L_{j_1} \setminus L_{(j_1+1)}$ . Since the induced map

$$H_{j_1}/H_{(j_1+1)} \to L_{j_1}/L_{(j_1+1)}$$

is surjective, there is an  $h'_1 \in H_{j_1}$  so that  $f(h'_1) \equiv f(h_0)^{-1}\ell$  modulo  $L_{(j_1+1)}$ . Set  $h_1 := h_0 h'_1$ . Now,

$$f(h_1) \equiv f(h_0)f(h'_1) \text{ modulo } L_{j_1+j_0}.$$

Thus,  $f(h_1) \equiv \ell \mod L_{j_1+1}$ .

Choose  $j_2 > j_1$  so that  $f(h_1)^{-1}\ell \in L_{j_2} \smallsetminus L_{(j_2+1)}$ . Since the induced map

$$H_{j_2}/H_{(j_2+1)} \to L_{j_2}/L_{(j_2+1)}$$

is surjective, there is an  $h'_2 \in H_{j_2}$  so that  $f(h'_2) \equiv f(h_1)^{-1}\ell$  modulo  $L_{(j_2+1)}$ . Set  $h_2 := h_1 h'_2$ . Then

$$f(h_2) \equiv f(h_1)f(h'_2) \mod L_{j_2+j_1}.$$

Thus,  $f(h_2) \equiv \ell \mod L_{j_2+1}$ .

Continuing in this fashion, we produce a convergent sequence  $(h_i)$  in H. If  $h = \lim h_i$ , then  $f(h) = \ell$ .

LEMMA B.6.15. For all facets  $J \subset \mathcal{B}(G)$  and for all s > 0 we have  $\psi(G_{x_J,s}) = \mathfrak{g}_{x_J,s}$ .

*Proof.* From Lemma B.5.4 we may assume that  $s \ge 1/n$ . Thanks to Corollary B.6.5 it suffices to prove surjectivity.

Choose  $m' \in \mathbb{Z}_{\geq 1}$  so that J is  $F^{m'}$ -stable. We let  $x = x_J$ . It will be enough to show that for all  $m \in \mathbb{Z}_{\geq m'}$ 

$$\psi(G_{x,s}^{F^m}) = \mathfrak{g}_{x,s}^{F^m}.$$

Note that  $G_{x,s}^{F^m}$  and  $\mathfrak{g}_{x,s}^{F^m}$  are complete topological groups. Thanks to Corollary B.6.5, Lemma B.6.7, and Lemma B.6.12, the result follows from Lemma B.6.13.

COROLLARY B.6.16.

$$\psi(G_{0^+}) = \mathfrak{g}_{0^+}.$$

*Proof.* From Lemma B.6.15, for all facets J in  $\mathcal{B}(G)$  we have  $\psi(G_J^+) = \mathfrak{g}_J^+$ . Since

$$G_{0^+} = \bigcup_J G_J^+$$
 and  $\mathfrak{g}_{0^+} = \bigcup_J \mathfrak{g}_J^+$ ,

the result follows.

The map over the residue field induced by  $\psi$ .

LEMMA B.6.17. Suppose  $x \in \mathcal{B}(G)$ . If  $t \geq 1/n$  and  $g \in G_{x,t}$ , then for all  $q \in \mathbb{R}$  and for each  $Q \in \mathfrak{g}_{x,q}$ ,

$$\log(\operatorname{Ad}(g))Q \equiv -\sum_{m=1}^{2(n-1)} \frac{(1 - \operatorname{Ad}(g))^m}{m}Q$$

modulo  $\mathfrak{g}_{x,(q+2-1/n)}$ .

*Proof.* Fix  $t \geq 1/n$  and  $g \in G_{x,t}$ . Suppose  $q \in \mathbb{R}$  and  $Q \in \mathfrak{g}_{x,q}$ . For all  $m \in \mathbb{Z}_{\geq 1}$ ,

$$\frac{(1 - \operatorname{Ad}(g))^m}{m} Q \in \mathfrak{g}_{x,(q+mt-\nu(m))}$$

891

Since  $p \ge (2+e)n$ , we conclude that for  $1 \le m \le (3n-2)$ ,

$$\frac{(1 - \operatorname{Ad}(g))^m}{m} Q \in \mathfrak{g}_{x,(q+mt)}$$

(since m is a unit). In particular, as  $t \ge 1/n$ , we conclude that

$$\sum_{m=1}^{2(n-1)} \frac{(1 - \operatorname{Ad}(g))^m}{m} Q \equiv \sum_{m=1}^{(3n-2)} \frac{(1 - \operatorname{Ad}(g))^m}{m} Q \mod \mathfrak{g}_{x,(q+2-1/n)}.$$

To finish the proof, it is enough to show that if  $m \ge (3n-1)$ , then  $mt - \nu(m) \ge 2 - 1/n$ . This follows from Remark B.6.3.

LEMMA B.6.18. Suppose  $J \subset \mathcal{B}(G)$  is a facet and  $C \subset \mathcal{B}(G)$  is an alcove which contains J in its closure. If  $g \in G_C^+$  and  $h \in G_J^+$ , then

$$\psi(gh) \in \psi(g) + \mathfrak{g}_J^+.$$

*Proof.* Since  $G_J^+ \leq G_C^+$ , both g and gh belong to  $G_C^+ = G_{x_C,1/n}$  (see Lemma B.5.4). Consequently, from Lemma B.6.15, both  $\psi(g)$  and  $\psi(gh)$  belong to  $\mathfrak{g}_C^+ \leq \mathfrak{g}_J$ . Hence, the images of  $\psi(g)$  and  $\psi(gh)$  in  $\mathsf{L}_J$  belong to the nilradical of the Borel subgroup of  $\mathsf{G}_J$  corresponding to C. Hence, they both belong to the derived Lie algebra of  $\mathsf{L}_J$ . Since the restriction of B to  $\mathfrak{g}_J$  induces the Killing form on the derived Lie algebra of  $\mathsf{L}_J$ , it will be enough to show that for all  $Q \in \mathfrak{g}_J$ ,

$$[\mathrm{ad}(\psi(gh)) - \mathrm{ad}(\psi(g))]Q \in \mathfrak{g}_{J}^{+}.$$

Fix  $Q \in \mathfrak{g}_J$ . Since  $\varpi Q \in \mathfrak{g}_J^+$ ,

$$Q \in \varpi^{-1} \mathfrak{g}_J^+ \le \varpi^{-1} \mathfrak{g}_C^+ = \mathfrak{g}_{x_C, 1/n-1}.$$

From Lemma B.6.17 and Equation (44),

$$\mathrm{ad}(\psi(gh))Q = \log(\mathrm{Ad}(gh))Q \equiv -\sum_{m=1}^{2(n-1)} \frac{(1 - \mathrm{Ad}(gh))^m}{m}Q$$

modulo  $\mathfrak{g}_{x_C,1} = \varpi \mathfrak{g}_C \leq \varpi \mathfrak{g}_J \leq \mathfrak{g}_J^+$ . (Note: *m* is a unit for  $1 \leq m \leq 2(n-1)$ .) Similarly,

$$\mathrm{ad}(\psi(g))Q \equiv -\sum_{m=1}^{2(n-1)} \frac{(1-\mathrm{Ad}(g))^m}{m}Q$$

modulo  $\mathfrak{g}_J^+$ . Consequently,

$$[\mathrm{ad}(\psi(gh) - \psi(g))]Q \equiv \sum_{m=1}^{2(n-1)} \left[ \frac{(1 - \mathrm{Ad}(g))^m - (1 - \mathrm{Ad}(gh))^m}{m} \right] Q$$

modulo  $\mathfrak{g}_J^+$ . Since h acts trivially on  $\mathfrak{g}_J/\mathfrak{g}_J^+$ ,

$$(1 - \operatorname{Ad}(gh))^m Q \equiv (1 - \operatorname{Ad}(g))^m Q$$

modulo  $\mathfrak{g}_J^+$ . The result follows.

COROLLARY B.6.19. Suppose J is an F-stable facet in  $\mathcal{B}(G)$ . The restriction of  $\psi$  to  $G_{0^+} \cap G_J$  induces an  $\langle F \rangle \ltimes \mathsf{G}_J$ -equivariant bijective map from  $\mathcal{U}_J$ , the f-variety of unipotent elements in  $\mathsf{G}_J$ , to  $\mathcal{N}_J$ , the f-variety of nilpotent elements in  $\mathsf{L}_J$ .

*Proof.* If  $\bar{g} \in \mathcal{U}_J$ , then there exist an alcove C and a  $g \in G_C^+$  such that  $J \subset \bar{C}$  and g is a lift of  $\bar{g}$ . From Lemma B.6.15 we have  $\psi(g) \in \mathfrak{g}_C^+ \subset \mathfrak{g}_J$ . Thus, the image of  $\psi(g)$  in  $L_J$  belongs to  $\mathcal{N}_J$ . From Lemma B.6.18, the image of  $\psi(g)$  in  $L_J$  is independent of the choice of g. Hence  $\psi$  induces a map  $\bar{\psi} \colon \mathcal{U}_J \to \mathcal{N}_J$ . As  $\psi$  is  $\langle F \rangle \ltimes G_J$ -equivariant, it follows that  $\bar{\psi}$  is  $\langle F \rangle \ltimes G_J$ -equivariant.

To see that  $\psi: \mathcal{U}_J \to \mathcal{N}_J$  is bijective, we note that  $p \geq (2+e)n$  implies (see for example [12, §1.15]) that there is a (nonunique) bijective,  $\mathsf{G}_J$ -equivariant f-morphism identifying  $\mathcal{U}_J$  with  $\mathcal{N}_J$ . Thus, for all  $m \in \mathbb{Z}_{\geq 1}$  the sets  $\mathcal{U}_J^{F^m}$  and  $\mathcal{N}_J^{F^m}$  have the same cardinality. Consequently, it is enough to show that the restriction to  $\mathcal{U}_J^{F^m}$  of  $\bar{\psi}$  surjects onto  $\mathcal{N}_J^{F^m}$ . If  $\bar{X} \in \mathcal{N}_J^{F^m}$ , then there exist an  $F^m$ -stable alcove C and  $X \in (\mathfrak{g}_C^+)^{F^m}$  such that  $J \subset \bar{C}$  and X is a lift of  $\bar{X}$ . From the proof of Lemma B.6.15 there exists a  $g \in (G_C^+)^{F^m}$  such that  $\psi(g) = X$ .

Since  $\mathcal{U}_J$  is the image of  $G_{0^+} \cap G_J$  in  $\mathsf{G}_J$ , the corollary follows.  $\Box$ 

B.7. An extension to reductive groups. Drop the assumption that **G** is semisimple. In this section, we prove that the  $\langle F \rangle \ltimes G$ -equivariant map  $\psi: G_{0^+} \to \mathfrak{g}$  has the properties described in Lemma B.0.3.

Let G' denote the group of K-rational points of the derived group of  $\mathbf{G}$ . Let Z denote the group of K-rational points of  $\mathbf{Z}$ , the identity component of the center of  $\mathbf{G}$ . We recall that  $Z \cap G'$  is finite. We let  $\mathfrak{g}'$  (resp.  $\mathfrak{z}$ , resp.  $\mathfrak{z}$ ) denote the Lie algebra of G' (resp. Z, resp.  $\mathbf{Z}$ ).

In Section B.6 we proved that the map

 $\operatorname{res}_{G'}\psi\colon G'_{0^+}\to \mathfrak{g}'$ 

has the properties required by Lemma B.0.3. From [9, III, §7, Prop. 11],

(47) 
$$\psi(zh) = \psi(z) + \psi(h)$$

for all  $z \in Z_{0^+}$  and all  $h \in G'_{0^+}$ .

Suppose **S** is any torus in **G**. Let *S* denote the group of *K*-rational points of **S**. Let  $\mathfrak{s}$  (resp.  $\mathfrak{s}$ ) denote the Lie algebra of *S* (resp. **S**).

LEMMA B.7.1. With our assumptions on p,

$$\psi(S_{0^+}) = \mathfrak{s}_{0^+}$$

*Proof.* Let E denote the splitting field of  $\mathbf{S}$  over K. Since  $\varphi : \mathbf{G} \to \mathrm{GL}_n$  is faithful and  $\varphi(\mathbf{S})$  is a torus in  $\mathrm{GL}_n$ , the field E is a tame Galois extension of K and  $\nu_E(p) \leq n\nu(p)$ .

Since E is a tame Galois extension of K, from [2, Lemma 2.2.3], we have

$$S_{0^+} = \mathbf{S}(E)_{0^+} \cap S.$$

By an argument similar to that given in Section B.3, there is a unique  $\operatorname{Gal}(E/K) \ltimes \mathbf{G}(E)$ -equivariant extension of  $\psi$  to a map  $\psi \colon \mathbf{G}(E)_{0^+} \to \mathbf{g}(E)$ . From Equation (44) the image of the restriction to  $\mathbf{S}(E)_{0^+}$  of this map lies in  $\mathbf{\mathfrak{s}}(E)$ . It will be enough to show that  $\psi(\mathbf{S}(E)_{0^+}) = \mathbf{\mathfrak{s}}(E)_{0^+}$ .

Since **S** is *E*-split, there is an *E*-isomorphism  $\varphi_S$  from **S** to  $(GL_1)^j$  for some *j*. Since

$$p \ge (2 + \nu(p))n \ge 2n + \nu_E(p),$$

we have  $p \ge 2 + \nu_E(p)$ . We conclude (see the discussion concerning  $GL_n$  in §B.1) that

$$\log((\operatorname{GL}_1(E))_{0^+}^j) = (M_1(E))_{0^+}^j$$

Since  $\varphi_S$  and  $d\varphi_S$  are *E*-isomorphisms, the result follows from the fact that  $d\varphi_S(\psi(s)) = \log(\varphi_S(s))$  for  $s \in \mathbf{S}(E)_{0^+}$  (see Equation (41)).

LEMMA B.7.2. Under our assumptions on p, the map  $(z,h) \mapsto zh$  from  $Z_{0^+} \times G'_{0^+}$  to  $G_{0^+}$  is bijective.

The proof below is due to Loren Spice; it is shorter than our original proof.

*Proof* (Spice). Since for each  $x \in \mathcal{B}(G)$  we have  $Z_{0^+} \subseteq G_{x,0^+}$  and  $G'_{x,0^+} \subseteq G_{x,0^+}$ , it suffices to check that the map  $i_x \colon Z_{0^+} \times G'_{x,0^+} \to G_{x,0^+}$  which sends (z,h) to zh is bijective for all  $x \in \mathcal{B}(G)$ .

Fix  $x \in \mathcal{B}(G)$ . To show  $i_x$  is bijective, it is enough to check that the induced map on successive quotients of Moy-Prasad filtration subgroups is bijective. Fix  $r \in \mathbb{R}_{>0}$ . From [64, Cor. 2.4], it is enough to check that the induced map

$$\mathfrak{z}_r/\mathfrak{z}_{r^+} imes\mathfrak{g}_{x,r}'/\mathfrak{g}_{x,r^+}
ightarrow\mathfrak{g}_{x,r^+}$$

is bijective. From [4, Prop. 3.2], it is surjective. If  $(\overline{Z}, \overline{X})$  is in its kernel, then there exist  $Z \in \mathfrak{z}_r$  (resp.,  $X \in \mathfrak{g}'_{x,r}$ ) lifting  $\overline{Z}$  (resp.,  $\overline{X}$ ) so that  $Z + X \in \mathfrak{g}_{x,r^+}$ . From [4, Prop. 3.2], we conclude that  $Z \in \mathfrak{z}_{r^+}$  and  $X \in \mathfrak{g}'_{x,r^+}$ . Thus, the map is injective as well.

Thanks to Equation (47), from Lemma B.7.1 and Lemma B.7.2, the map  $\psi$  is a bijective  $\langle F \rangle \ltimes G$ -equivariant map from  $G_{0^+}$  to  $\mathfrak{g}_{0^+} = \mathfrak{z}_{0^+} + \mathfrak{g}'_{0^+}$ . Moreover, since, for all  $x \in \mathcal{B}(G)$ , the image of  $\mathfrak{z}_{0^+}$  in  $L_x$  is trivial, it follows from Lemma B.7.1 (with S = Z) that  $\psi$  has the properties required by Lemma B.0.3.

$J_{\lambda}$	facet in $\mathcal{A}$ preserved by $\sigma_{\lambda}$	813
k	finite extension of $\mathbb{Q}_p$	802
K	maximal unramified extension of $k$	802
$\kappa^0_\lambda$	$\epsilon(G_{\lambda},T_{\lambda})\cdot R^{G_{\lambda}}_{T_{\lambda},\chi^{0}_{\lambda}}\in\mathrm{Irr}(G^{\mathrm{F}_{\lambda}}_{\lambda})$	830
$\kappa_\lambda$	representation of $Z^{\mathrm{F}}G_{\lambda}^{\mathrm{F}_{\lambda}}$	830
$L_J$	Lie algebra of $G_J$ ; identified with $\mathfrak{g}_J/\mathfrak{g}_J^+$	834
$m_{\lambda}$	element of N for which $m_{\lambda} * u_{\lambda} = u$ and $m_{\lambda} \cdot C_{\lambda} = C$	815

TTE		
$\mu^{H^F}_X(f) \ \hat{\mu}^{H^F}_X$	$H^F$ -orbital integral of $f$ with respect to $X$	863
	function representing Fourier transform of $\mu_X^{H^F}$	863
N(G,S)	normalizer of a subgroup $S \subset G$	802
N	N(G,T)	804
$N_o$	$N \cap G_o$	804
N(i)	$ N(G_{\gamma_{s}}, S^{F})/S $ , where $S \in \mathcal{T}_{st}(\gamma_{s}, i)$	859
$\Omega_C$	$\{\omega \in W : \ \omega \cdot C = C\}$ for some alcove $C$ in $\mathcal{A}$	804
$\omega_{\lambda}$	unique element of $t_{\lambda}W^{\circ} \cap \Omega_C$	810
$\dot{\omega}_{\lambda}$	element of $Z^1(\mathbf{F}, N_C)$ with image $\omega_{\lambda}$ in W	811
$\omega$	fixed element of $H^1(\mathbf{F}, G)$	815
0	F-fixed hyperspecial vertex in $\mathcal{A}_{ad}$	804
p	characteristic of the residue field $\mathfrak{f}$	802
$p_{\lambda}$	element of $G_{\lambda}$ for which $p_{\lambda}^{-1} F_{\lambda}(p_{\lambda}) = \dot{w}_{\lambda}$	815
$\pi_{\lambda}$	$\operatorname{Ind}_{Z^{\mathrm{F}}G^{\mathrm{F}_{\lambda}}}^{G^{\mathrm{F}_{\lambda}}}\kappa_{\lambda}$	831
$\pi_u(\varphi, \rho)$	$\operatorname{Ad}(m_{\lambda})_{*}\pi_{\lambda} \in \operatorname{Irr}(G^{\operatorname{F}_{u}})$	834
$\Pi_u(\varphi)$	normalized L-packet	834
$p_1$	surjective projection onto first factor: $\hat{\mathcal{T}}_{v,\chi} \longrightarrow \mathcal{T}_{v}$	851
$p_2$	projection on second factor: $p_1^{-1}(S) \longrightarrow \operatorname{Irr}_0(S^F)$	851
$\overline{q}$	cardinality of the residue field f	802
	$m_{\lambda}p_{\lambda}\in G$	816
$\stackrel{q_{m{\lambda}}}{\dot{Q}_{m{S}}^{({G}_J)_{\overline{\gamma}_{\mathbf{s}}}}}$	natural inflation of $Q_{S}^{(G_J)_{\overline{\gamma}_{\mathrm{s}}}}$ , extended by zero to $G^F$	854
$Q(G_{\gamma_{\mathrm{s}}}, \mathcal{T}_{\mathrm{st}}^{1})$	stable $p$ -adic analogue of a Green function	859
r	map $X_w \to H^1(\mathbf{F}, \mathbf{G})$	815
$[r^{-1}(\omega)]$	image of $r^{-1}(\omega)$ in $[X/(1-w\vartheta)X]_{\text{tor}}$	817
$R(G, S, \theta)$	function on $(G^{rss})^F$	848
$R(G, \mathcal{T})$	$R(G, S, \theta)$ , where $\mathcal{T}$ is the $G^F$ -orbit of $(S, \theta)$	848
$R(G, \hat{\mathcal{T}}_{\mathrm{st}})$	$\sum_{(S,\theta)\in\hat{\mathcal{I}}_{\mathrm{st}}/G^F} R(G,S,\theta)$	851
s	homomorphism $s: \mathcal{I}_t \longrightarrow \hat{T}$ with $C_{\hat{G}}(s) = \hat{T}$	825
$^{0}S$	maximal bounded subgroup of an unramified torus $S$	803
$\sigma_{\lambda}$	$t_{\lambda}w\vartheta \in W \rtimes \langle \vartheta \rangle$	812
$S_{\lambda}$	$\operatorname{Ad}(q_{\lambda})T$	816
$\hat{St}$	Steinberg representation	798
$\hat{S}^{\mathfrak{h}}_X$	Fourier transform of the stable orbital integral	864
Т	associated to $X$ fixed maximally k-split K-split torus in <b>G</b>	804
$\overline{^{0}T}$	maximal bounded subgroup of $T$	804
	Ad $(p_{\lambda})T$	830
$T_\lambda \ \hat{T}$	$Y\otimes \mathbb{C}^{ imes}$	811
$t_{\lambda}$	element of T or W corresponding to $\lambda \in X$	804
$\mathfrak{T}(G)$	set of $F$ -minisotropic maximal tori in $G$	846
$\hat{\mathfrak{T}}(G)$ $\hat{\mathfrak{T}}(G)$	$\{(S,\theta): S \in \mathfrak{T}(G) \text{ and } \theta \in \operatorname{Irr}_0(S^F)\}$	850
$\mathcal{Z}(\mathbb{C}^{r})$ $\mathcal{T}_{v}$	$\{S \in \mathfrak{T}(G) : S^F = {}^g(T^{F_v}) \text{ for some } g \in G\}$	850
U		

$\hat{\mathcal{T}}_{v,\chi}$	$(S, \theta)$ for which there is $g \in G$ so that $S^F = {}^g(T^{F_v})$	850
	and $\theta = g_* \chi$	
$\hat{\mathcal{T}}_{\mathrm{st}} \ \hat{\mathcal{T}}$	fixed G-stable class in $\hat{\mathfrak{T}}(G)$	851
$\hat{T}$	$G^F$ -orbit in $\mathfrak{T}(G)$	854
$\hat{\mathcal{T}}(\gamma_{\mathrm{s}})$	$\{(S', \theta') \in \hat{\mathcal{T}}: \gamma_{\mathrm{s}} \in S'\}$	854
$\hat{\mathcal{T}}_{ m st}(\gamma_{ m s})$	$\{(S, heta)\in\hat{T}_{\mathrm{st}}: \ \gamma_{\mathrm{s}}\in S\}$	859
$\hat{\mathcal{T}}_{\mathrm{st}}(\gamma_{\mathrm{s}}) \\  heta_{S}^{\chi}$	$\sum_{ heta \ \in \ p_2 p_1^{-1}(S)}  heta$	851
$ heta_i^\chi(\gamma_{ m s})$	$\theta_S^{\chi}(\gamma_{\rm s})$ , for any $S \in \mathcal{T}_{\rm st}(\gamma_{\rm s}, i)$	860
$\Theta_{\rho_{\lambda}}$	character of $\pi_u(\varphi, \rho_\lambda)$	853
u	fixed representative of $\omega$	815
$\overline{\omega}$	fixed uniformizer of $k$	802
$\vartheta$	automorphism of $X, X_{ad}, \mathcal{A}, \mathcal{A}_{ad}, W, \text{ or } W_{ad}$	804
${\mathcal W}$	Weil group of $k$	821
$\mathcal{W}_t$	tame Weil group	821
W	$N/^0T$	804
$W^{\circ}$	generated by reflections in the walls of an alcove ${\cal C}$	804
$W_o$	image of $N_o$ in $W$	804
$\dot{W}_o$	Tits extension of $W_o$	812
$W_{\lambda}$	generated by reflections in hyperplanes containing $J_{\lambda}$	813
$W_o^{w\vartheta}$	$\{z_o \in W_o: \ w\vartheta(z_o)w^{-1} = z\}$	818
$ \begin{array}{c} W^{w\vartheta}_o \\ W^{w\vartheta}_{o,\lambda} \end{array} $	stabilizer in $W_o^{w\vartheta}$ of the class of $\lambda$ in $[r^{-1}(\omega)]$	819
w	element of $W_o$	812
$\dot{w}$	fixed lift in $\dot{W}_o$ of $w$	814
$w_{\lambda}$	unique element in $W_{\lambda}$ for which $\sigma_{\lambda} \cdot C_{\lambda} = w_{\lambda} \cdot C_{\lambda}$	813
$\dot{w}_{\lambda}$	unique lift of $w_{\lambda}$ in N satisfying $t_{\lambda}\dot{w} = \dot{w}_{\lambda}u_{\lambda}$	814
$x_{\lambda}$	unique fixed-point in $\mathcal{A}$ for $t_{\lambda}w\vartheta$	796
$X_*(\mathbf{H})$	group of algebraic one-parameter subgroups of ${f H}$	803
X	$X_*(\mathbf{T})$	804
$X^{\circ}$	co-root sublattice in $X$	804
$\bar{X}$	$X/X^{\circ}$	810
$X_w$	preimage in X of $[X/(1-w\vartheta)X]_{tor}$	812
$\chi_{arphi}$	depth zero character corresponding to $\varphi$	827
$\chi_{\lambda}$	$\operatorname{Ad}(p_{\lambda})_*\chi \in \operatorname{Irr}(T_{\lambda}^{\mathcal{F}_{\lambda}})$	830
Y	algebraic character group of $\mathbf{T}$	811
$y_{\lambda}$	$w_{\lambda}^{-1}t_{\lambda}w$	813
$Z^1(F,U)$	continuous cocycles $\Gamma \longrightarrow U$	805
$\hat{Z}$	center of $\hat{G}$	811
