# $p$-adic $L$-functions and Selmer varieties associated to elliptic curves with complex multiplication 

By Minhyong Kim

#### Abstract

We show how the finiteness of integral points on an elliptic curve over $\mathbb{Q}$ with complex multiplication can be accounted for by the nonvanishing of $L$-functions that leads to bounds for dimensions of Selmer varieties.

The study of non-abelian fundamental groups renders it plausible that the principle of Birch and Swinnerton-Dyer, whereby nonvanishing of $L$-values, in some appropriate sense, accounts for the finiteness of integral points, can eventually be extended to hyperbolic curves. Here we will discuss the very simple case of a genus 1 hyperbolic curve $X / \mathbb{Q}$ obtained by removing the origin from an elliptic curve $E$ defined over $\mathbb{Q}$ with complex multiplication by an imaginary quadratic field $K$. Denote by $\mathscr{E}$ a Weierstrass minimal model of $E$ and by $\mathscr{X}$ the integral model of $X$ obtained as the complement in $\mathscr{E}$ of the closure of the origin. Let $S$ be a set of primes including the infinite place and those of bad-reduction for $\mathscr{E}$. We wish to examine the theorem of Siegel, asserting the finiteness of $\mathscr{X}\left(\mathbb{Z}_{S}\right)$, the $S$-integral points of $\mathscr{X}$, from the point of view of fundamental groups and Selmer varieties. In particular, we show how the finiteness of points can be proved using 'the method of Coates and Wiles' which, in essence, makes use of the nonvanishing of $p$-adic $L$-functions arising from the situation.

That is to say, in studying the set $\mathscr{E}\left(\mathbb{Z}_{S}\right)(=\mathscr{E}(\mathbb{Z})=E(\mathbb{Q}))$, Coates and Wiles showed the special case of the conjecture of Birch and Swinnerton-Dyer by deriving the finiteness of $\mathscr{E}\left(\mathbb{Z}_{S}\right)$ from the nonvanishing of $L(E / \mathbb{Q}, s)$ at $s=1$. Of course the $L$-function can vanish at 1 in general, in which case $\mathscr{E}\left(\mathbb{Z}_{S}\right)$ is supposed to be infinite. But we know that $\mathscr{X}\left(\mathbb{Z}_{S}\right)$ is always finite. From the perspective of this paper, this is a consequence of the fact that appropriate $p$-adic $L$-functions have only finitely many zeros. More precisely, if we choose a prime $p$ that splits as $p=\pi \bar{\pi}$ in $K$ and let $\mathscr{L}$ and $\overline{\mathscr{L}}$ denote the $p$-adic $L$-functions associated to the $\pi$ and $\bar{\pi}$-power torsion points of $E / K$ [6], we know that they have only finitely many zeros. Then the nonvanishing of $L$-functions forces the vanishing of infinitely many

$\mathbb{Q}_{p}$-Selmer groups for a family of Galois representations naturally associated to $X$. The motivic tool used to put this information together in the present approach is a natural quotient

## W

of the $\mathbb{Q}_{p}$-pro-unipotent fundamental group $U$ of $X$ with basepoint at an $S$-integral point $b$ (which we assume to exist) and, as usual, its further quotients $W_{n}$ modulo the descending central series. Integral points of $\mathscr{X}$ give rise to torsors for the $W_{n}$ that are classified by a projective system of global Selmer varieties

$$
H_{f}^{1}\left(\Gamma, W_{n}\right),
$$

where $\Gamma=\operatorname{Gal}(\overline{\mathbb{Q}} / \mathbb{Q})$ is the Galois group over $\mathbb{Q}$ of an algebraic closure. That is, there is a diagram

obtained from the formalism of the fundamental group that associates to each point $x$ the $U$-torsor of paths from $b$ to $x$ and then pushes it out to a $W_{n}$-torsor. Here, $\Gamma_{p}=\operatorname{Gal}\left(\overline{\mathbb{Q}}_{p} / \mathbb{Q}_{p}\right)$ embedded into $\Gamma$ as a decomposition group at $p$.

Let $G=\operatorname{Gal}\left(K\left(E\left[\pi^{\infty}\right]\right) / K\right)$ and $\bar{G}=\operatorname{Gal}\left(K\left(E\left[\bar{\pi}^{\infty}\right]\right) / K\right)$, and let $\Lambda=$ $\mathbb{Z}_{p}[[G]], \bar{\Lambda}=\mathbb{Z}_{p}[[\bar{G}]]$ be the corresponding Iwasawa algebras, so that $\mathscr{L} \in \Lambda$ and $\overline{\mathscr{L}} \in \bar{\Lambda}$. Denote by

$$
\chi: \Lambda \rightarrow \mathbb{Q}_{p}, \quad \bar{\chi}: \bar{\Lambda} \rightarrow \mathbb{Q}_{p}
$$

the homomorphisms corresponding to the Galois actions on

$$
\left.\left.V_{\pi}(E)=\left(\underset{\leftarrow}{\lim } E\left[\pi^{n}\right]\right) \otimes \mathbb{Q}\right) \quad \text { and } \quad V_{\bar{\pi}}(E)=\left(\underset{\leftarrow}{\lim } E\left[\bar{\pi}^{n}\right]\right) \otimes \mathbb{Q}\right) .
$$

Finally, let $r=\operatorname{dim} H_{f}^{1}\left(\Gamma, V_{p}(E)\right)$ and $s=|S|$.
THEOREM 0.1. We have the inequality of dimensions

$$
\operatorname{dim} H_{f}^{1}\left(\Gamma, W_{n}\right)<\operatorname{dim} H_{f}^{1}\left(\Gamma_{p}, W_{n}\right)
$$

for all $n$ sufficiently large.
The fact that the $p$-adic $L$-functions can have at most finitely many zeros is exactly the required input for this theorem. But the location of the zeros, of course, is a highly nontrivial issue. On the other hand,

Theorem 0.2. Suppose $\chi^{k}(\mathscr{L}) \neq 0$ and $\bar{\chi}^{k}(\overline{\mathscr{L}}) \neq 0$ for each $k<0$. Then

$$
\operatorname{dim} H_{f}^{1}\left(\Gamma, W_{n}\right)<\operatorname{dim} H_{f}^{1}\left(\Gamma_{p}, W_{n}\right)
$$

for all $n \geq r+s+1$.
I am informed by John Coates that the nonvanishing in the hypothesis is a conjecture appearing in folklore.

The way the implication works out is that each nonvanishing of an $L$-value implies the vanishing of some $H^{2}$ in Galois cohomology, and $W$ is constructed so as to avoid the complications that arise when working directly with $U$. The finiteness of global points then follows in a straightforward way as in previous work (e.g., [4]) whereby the inequality implies the existence of certain $p$-adic iterated integrals that vanish on the global points. Since we hope the method will eventually lead to a direct construction of a $p$-adic analytic function that annihilates the global points, the more refined statement of the second theorem seems worth making explicit. Of course in the present work the main emphasis is the sequence of implications

Non-vanishing of $L$-values $\Rightarrow$ control of Selmer varieties $\Rightarrow$ finiteness of global points,
entirely parallel to the case of rational points on compact elliptic curves, with just the replacement of Selmer groups by Selmer varieties.

A word of caution regarding the notation: At the urging of Richard Hain, the indexing of the finite-dimensional quotients of $U$ has been shifted, so our $U_{n}$ is $U_{n+1}$ from the papers [4] and [5], for example. However, the scheme here is consistent with that of [3].

## 1. A quotient of the unipotent fundamental group

The quotient in question is constructed as follows. Let $U=\pi_{1}^{u n}(\bar{X}, b)$ be the $\mathbb{Q}_{p}$-pro-unipotent completion of $\hat{\pi}_{1}(\bar{X}, b)$ (see [2]) and let $U^{n}$ denote the descending central series, normalized so that $U^{1}=U$. Define $U_{n}=U^{n+1} \backslash U$. We then have exact sequences

$$
0 \rightarrow U^{n+1} \backslash U^{n} \rightarrow U_{n} \rightarrow U_{n-1} \rightarrow 0
$$

for $n \geq 1$. Denote by $L$ the Lie algebra of $U$ with descending central series $L^{n}$. Thus, we have natural isomorphisms

$$
U^{n+1} \backslash U^{n} \simeq L^{n+1} \backslash L^{n}
$$

compatible with the action of $\Gamma$. Since $\hat{\pi}_{1}(\bar{X}, b)$ is pro-finite free on two generators, $L$ is the pro-nilpotent completion of the free Lie algebra on two generators, where the generators can be any two elements projecting to a basis of $L_{1}=H_{1}\left(\bar{X}, \mathbb{Q}_{p}\right)$. Therefore, $L$ comes with a natural grading (not compatible with the Galois action)

$$
L=\overline{\oplus_{n=1}^{\infty} L(n)}
$$

where $L(n)$ is generated by the Lie monomials of degree $n$ in the generators [7]. On the other, in the current situation, we have

$$
L_{1}=V_{p}(E) \simeq V_{\pi}(E) \oplus V_{\bar{\pi}}(E)
$$

so that $L$ even has a bi-grading

$$
L=\overline{\oplus L_{i, j}}
$$

That is, taking $e$ and $f$ to be elements in $L_{1}$ that map to bases of $V_{\pi}$ and $V_{\bar{\pi}}$ respectively, $L_{i, j}$ is spanned by Lie monomials that have $i$ number of $e$ 's and $j$ number of $f$ 's, e.g.,

$$
\operatorname{ad}^{i-1}(e)\left(\operatorname{ad}^{j-1}(f)([e, f])\right)
$$

This bi-grading also induces a filtration

$$
L_{\geq n, \geq m}:=\overline{\oplus_{i \geq n, j \geq m} L_{i, j}}
$$

by Lie ideals. Let $N=\operatorname{Gal}(\overline{\mathbb{Q}} / K) \subset \Gamma$ so that $\Gamma=N \sigma$, where $\sigma$ is complex conjugation. Then if $x \in N$, we have

$$
x e=\chi(x) e+z \quad \text { and } \quad x f=\bar{\chi}(x) f+z^{\prime}
$$

for $z, z^{\prime} \in L^{2}$. But $L^{2} \subset L_{\geq 1, \geq 1}$. Hence, if $l \in L_{i, j}$, then an easy induction shows that

$$
x l=\chi(x)^{i} \bar{\chi}(x)^{j} l+z
$$

for $z \in L_{\geq i+1, \geq j+1}$. In particular, each $L_{\geq n, \geq m}$ is stabilized by $N$. Similarly,

$$
\sigma\left(L_{\geq i, \geq j}\right) \in L_{\geq j, \geq i}
$$

so we see that $L_{\geq n, \geq n}$ is stabilized by $\Gamma$ for each $n$. Therefore, we get a quotient Lie algebra

$$
L \rightarrow \mathscr{W}:=L / L_{\geq 2, \geq 2} \rightarrow 0
$$

and a corresponding quotient group $U \rightarrow W \rightarrow 0$ with a compatible $\Gamma$-action. If we choose the ordering $e<f$, then [ $e, f]$ is a Hall basis [7] for $L^{3} \backslash L^{2}$, and inside the Hall basis for $L^{n+1} \backslash L^{n}, n \geq 3$, are the elements

$$
\operatorname{ad}^{n-2}(e)([e, f]) \quad \text { and } \quad \operatorname{ad}^{n-2}(f)([e, f])
$$

All the other basis elements are clearly in $L_{\geq 2, \geq 2}$. Thus,

$$
W^{n+1} \backslash W^{n} \simeq W^{n+1} \backslash W^{n}
$$

is generated by the class of $\operatorname{ad}^{n-2}(e)([e, f])$ and $\operatorname{ad}^{n-2}(f)([e, f])$. That is, as $\Gamma$-modules, we have

$$
W^{n+1} \backslash W^{n} \simeq \mathbb{Q}_{p}\left(\chi^{n-2}(1)\right) \oplus \mathbb{Q}_{p}\left(\bar{\chi}^{n-2}(1)\right), \quad n \geq 2
$$

where $\sigma$ acts by sending the generator $\mathrm{ad}^{n-2}(e)([e, f])$ to $-\operatorname{ad}^{n-2}(f)([e, f])$.

## 2. The unipotent Albanese map

There are various ways to see that $W$ is unramified outside $S$ and crystalline at $p$. For example, by construction, the coordinate ring of $W$ is a subring of that of $U$, and hence, the conditions of being unramified or crystalline ( $[4, \S 2]$ ) are inherited from $U$.

Now we examine the unipotent Albanese map [4],

$$
\mathscr{X}\left(\mathbb{Z}_{S}\right) \rightarrow H^{1}\left(\Gamma, U_{n}\right)
$$

obtained by associating to $x \in \mathscr{X}\left(\mathbb{Z}_{S}\right)$ the class of the $U_{n}$-torsor

$$
P(x):=\pi_{1}^{u n}(\bar{X} ; b, x)
$$

of unipotent paths from $b$ to $x$. We will continue this map to

$$
\mathscr{X}\left(\mathbb{Z}_{S}\right) \rightarrow H^{1}\left(\Gamma, U_{n}\right) \rightarrow H^{1}\left(\Gamma, W_{n}\right)
$$

obtained by composing with the quotient map. At the level of torsors, the map

$$
H^{1}\left(\Gamma, U_{n}\right) \rightarrow H^{1}\left(\Gamma, W_{n}\right)
$$

is given by the pushout:

$$
Z \mapsto\left(Z \times W_{n}\right) / U_{n}
$$

Since the condition of being crystalline at $p([4, \S 2])$ merely signifies that a torsor has a $\Gamma_{p}$-invariant $B_{\text {cr }}$ point, this condition is clearly preserved by push-out. Thus we have an induced map

$$
H_{f}^{1}\left(\Gamma_{p}, U_{n}\right) \rightarrow H_{f}^{1}\left(\Gamma_{p}, W_{n}\right)
$$

where the subscript $f$ refers exactly to the subset

$$
H_{f}^{1}\left(\Gamma_{p}, W_{n}\right) \subset H^{1}\left(\Gamma_{p}, W_{n}\right)
$$

of cohomology classes that are crystalline. Similarly, the condition of being unramified at $v \notin T=S \cup\{p\}$ is preserved under pushout. Let $\Gamma_{T}$ denote the Galois group of the maximal extension of $\mathbb{Q}$ unramified outside $T$. By [3], the system

$$
H^{1}\left(\Gamma_{T}, W_{n}\right)
$$

has the structure of a pro-algebraic variety over $\mathbb{Q}_{p}$, as does the subsystem

$$
H_{f}^{1}\left(\Gamma_{T}, W_{n}\right) \subset H^{1}\left(\Gamma_{T}, W_{n}\right)
$$

classifying torsors that are unramified outside $T$ and crystalline at $p$. Thus we also have an induced map of global Selmer varieties

$$
H_{f}^{1}\left(\Gamma, U_{n}\right) \rightarrow H_{f}^{1}\left(\Gamma, W_{n}\right)
$$

giving rise to a commutative diagram

$$
\begin{array}{clc}
\mathscr{X}\left(\mathbb{Z}_{S}\right) & \rightarrow & \mathscr{X}\left(\mathbb{Z}_{p}\right) \\
\downarrow & & \downarrow \\
H_{f}^{1}\left(\Gamma, W_{n}\right) & \rightarrow & H_{f}^{1}\left(\Gamma_{p}, W_{n}\right) .
\end{array}
$$

Since each map

$$
\mathscr{X}\left(\mathbb{Z}_{p}\right) \rightarrow H_{f}^{1}\left(\Gamma_{p}, U_{n}\right)
$$

has Zariski dense image, so do the maps

$$
\mathscr{X}\left(\mathbb{Z}_{p}\right) \rightarrow H_{f}^{1}\left(\Gamma_{p}, W_{n}\right) .
$$

As in [3] and [4], this denseness is an important ingredient in extracting Diophantine finiteness out of the theorems.

## 3. Proof of the theorems

The proof is now straightforward. Recall that we have a sequence

$$
0 \rightarrow H^{1}\left(\Gamma_{T}, W^{n+1} \backslash W^{n}\right) \rightarrow H^{1}\left(\Gamma_{T}, W_{n}\right) \rightarrow H^{1}\left(\Gamma_{T}, W_{n-1}\right)
$$

which is exact in that the vector group kernel acts on the middle term with quotient variety being the image of the second map. Furthermore, if we examine

$$
H_{f}^{1}\left(\Gamma_{p}, W^{n+1} \backslash W^{n}\right) \simeq H_{f}^{1}\left(\Gamma_{p}, \mathbb{Q}_{p}\left(\chi^{n-2}(1)\right) \oplus \mathbb{Q}_{p}\left(\bar{\chi}^{n-2}(1)\right)\right),
$$

we see that all classes are crystalline for $n \geq 3$. This is because, for example, the crystalline classes in $H^{1}\left(\Gamma_{p}, \mathbb{Q}_{p}\left(\chi^{n-2}(1)\right)\right)$ are classified by

$$
D^{D R}\left(\mathbb{Q}_{p}\left(\chi^{n-2}(1)\right)\right) / F^{0},
$$

where $D^{D R}(\cdot)=\left[(\cdot) \otimes B_{D R}\right]^{\Gamma_{p}}$ is Fontaine's Dieudonné functor [1]. But

$$
\begin{equation*}
D^{D R}\left(\mathbb{Q}_{p}\left(\chi^{n-2}(1)\right)\right)=D^{D R}\left(\mathbb{Q}_{p}\left(\chi^{n-2}\right)\right)( \tag{1}
\end{equation*}
$$

and the Hodge filtration on $D^{D R}\left(\mathbb{Q}_{p}\left(\chi^{n-2}\right)\right)$ is nonpositive. Therefore, the Hodge filtration on $D^{D R}\left(\mathbb{Q}_{p}\left(\chi^{n-2}(1)\right)\right)$ is strictly negative. Then a simple dimension count shows that

$$
H_{f}^{1}\left(\Gamma_{p}, \mathbb{Q}_{p}\left(\chi^{n-2}(1)\right)\right)=H^{1}\left(\Gamma_{p}, \mathbb{Q}_{p}\left(\chi^{n-2}(1)\right)\right)
$$

for $n \geq 3$ and the previous exact sequence can be rewritten

$$
0 \rightarrow H^{1}\left(\Gamma_{T}, W^{n+1} \backslash W^{n}\right) \rightarrow H_{f}^{1}\left(\Gamma_{T}, W_{n}\right) \rightarrow H_{f}^{1}\left(\Gamma_{T}, W_{n-1}\right)
$$

for $n \geq 3$. For $n=2$, we have

$$
0 \rightarrow H_{f}^{1}\left(\Gamma_{T}, \mathbb{Q}_{p}(1)\right) \rightarrow H_{f}^{1}\left(\Gamma_{T}, W_{2}\right) \rightarrow H_{f}^{1}\left(\Gamma_{T}, W_{1}\right)
$$

and

$$
H_{f}^{1}\left(\Gamma_{T}, \mathbb{Q}_{p}(1)\right) \simeq\left(\mathbb{Z}_{S}^{*}\right) \otimes \mathbb{Q}_{p}
$$

(as in $[5, \S 2]$ ) so that

$$
\operatorname{dim} H_{f}^{1}\left(\Gamma_{T}, W_{2}\right) \leq r+s-1
$$

If we put this together, we get

$$
\operatorname{dim} H_{f}^{1}\left(\Gamma_{T}, W_{n}\right) \leq r+s-1+\Sigma_{i=3}^{n} \operatorname{dim} H^{1}\left(\Gamma_{T}, W^{i+1} \backslash W^{i}\right)
$$

for $n \geq 3$. As for the dimensions of the intervening $H^{1}$ 's, we have the Euler characteristic formula

$$
\operatorname{dim} H^{1}\left(\Gamma_{T}, W^{i+1} \backslash W^{i}\right)=\operatorname{dim} H^{2}\left(\Gamma_{T}, W^{i+1} \backslash W^{i}\right)+\operatorname{dim}\left(W^{i+1} \backslash W^{i}\right)^{-}
$$

where the superscript refers to the subspace where $\sigma$ acts as $(-1)$. However, $\sigma$ exchanges the one-dimensional factors of $\mathbb{Q}_{p}\left(\chi^{n-2}(1)\right) \oplus \mathbb{Q}_{p}\left(\bar{\chi}^{n-2}(1)\right)$ so that $\operatorname{dim}\left(W^{i+1} \backslash W^{i}\right)^{-}=1$.

Meanwhile, for the local cohomologies, we can calculate the dimensions explicitly. Firstly, we know that

$$
\operatorname{dim} H_{f}^{1}\left(\Gamma_{p}, W_{2}\right)=\operatorname{dim} H_{f}^{1}\left(\Gamma_{p}, U_{2}\right)=2
$$

([4, §4]). On the other hand, $H^{2}\left(\Gamma_{p}, W^{n+1} \backslash W^{n}\right)=0$ for $n \geq 3$ so that the map

$$
H^{1}\left(\Gamma_{p}, W_{n+1}\right) \rightarrow H^{1}\left(\Gamma_{p}, W_{n}\right)
$$

is surjective for $n \geq 3$. As remarked above, we also have $H_{f}^{1}\left(\Gamma_{p}, W^{n+1} \backslash W^{n}\right)=$ $H^{1}\left(\Gamma_{p}, W^{n+1} \backslash W^{n}\right)$ for $n \geq 3$. This implies that we have an exact sequence

$$
0 \rightarrow H_{f}^{1}\left(\Gamma_{p}, W^{n+1} \backslash W^{n}\right) \rightarrow H_{f}^{1}\left(\Gamma_{p}, W_{n}\right) \rightarrow H_{f}^{1}\left(\Gamma_{p}, W_{n-1}\right) \rightarrow 0
$$

for $n \geq 3$, where each $H_{f}^{1}\left(\Gamma_{p}, W^{n+1} \backslash W^{n}\right)$ has dimension 2. Thus

$$
\operatorname{dim} H_{f}^{1}\left(\Gamma_{p}, W_{n}\right)=2(n-2)+2=2 n-2
$$

for $n \geq 2$.
It remains to prove the following two claims.
CLAIM 3.1. $H^{2}\left(\Gamma_{T}, W^{n+1} \backslash W^{n}\right)=0$ for $n$ sufficiently large.
CLAIM 3.2. If $\chi^{k}(\Lambda) \neq 0$ and $\bar{\chi}^{k}(\bar{\Lambda}) \neq 0$ for $k<0$, then $H^{2}\left(\Gamma_{T}, W^{n+1} \backslash W^{n}\right)$ $=0$ for $n \geq 3$.

Since Claim 3.1 implies that

$$
\operatorname{dim} H^{1}\left(\Gamma_{T}, W^{n+1} \backslash W^{n}\right)=1
$$

for $n$ sufficiently large, we see that there is a constant such that

$$
H_{f}^{1}\left(\Gamma_{T}, W_{n}\right)=C+n
$$

while the local dimensions grow like $2 n$. Thus we get the statement of Theorem 0.1.
On the other hand, with Claim 3.2, we get

$$
\operatorname{dim} H_{f}^{1}\left(\Gamma_{T}, W_{n}\right) \leq r+s+n-2
$$

so that we get the desired inequality of dimensions as soon as

$$
r+s+n-2<2 n-2
$$

or $n \geq r+s+1$.
We proceed to prove the claims. Clearly it suffices to consider the Galois cohomology of $N_{T} \subset G_{T}$, where $N_{T}$ is the Galois group of the maximal extension of $K$ unramified outside the primes dividing $T$. For any continuous representation $M$ of $N_{T}$, we define the kernel Sha ${ }^{i}$ of the localization maps on cohomology as

$$
0 \rightarrow \operatorname{Sha}^{i}(M) \rightarrow H^{i}\left(N_{T}, M\right) \rightarrow \oplus_{v \mid T} H^{i}\left(N_{v}, M\right)
$$

where $N_{v} \subset N_{T}$ is a decomposition group for the prime $v$. Thus we have

$$
0 \rightarrow \operatorname{Sha}^{2}\left(W^{n+1} \backslash W^{n}\right) \rightarrow H^{2}\left(\Gamma_{T}, W^{n+1} \backslash W^{n}\right) \rightarrow \oplus_{v \mid T} H^{2}\left(N_{v}, W^{n+1} \backslash W^{n}\right)
$$

By local duality,

$$
\begin{aligned}
H^{2}\left(N_{v}, W^{n+1} \backslash W^{n}\right) & =H^{2}\left(N_{v}, \mathbb{Q}_{p}\left(\chi^{n-2}(1)\right) \oplus \mathbb{Q}_{p}\left(\bar{\chi}^{n-2}(1)\right)\right) \\
& \simeq H^{0}\left(N_{v}, \mathbb{Q}_{p}\left(\chi^{2-n}\right) \oplus \mathbb{Q}_{p}\left(\bar{\chi}^{2-n}\right)\right)^{*}=0
\end{aligned}
$$

for $n \geq 3$ from which we get

$$
\operatorname{Sha}^{2}\left(W^{n+1} \backslash W^{n}\right) \simeq H^{2}\left(N_{T}, W^{n+1} \backslash W^{n}\right)
$$

By Poitou-Tate duality, we have

$$
\begin{aligned}
\operatorname{Sha}^{2}\left(W^{n+1} \backslash W^{n}\right) & \simeq \operatorname{Sha}^{1}\left(\left(W^{n+1} \backslash W^{n}\right)^{*}(1)\right)^{*} \\
& \simeq \operatorname{Sha}^{1}\left(\mathbb{Q}_{p}\left(\chi^{2-n}\right)\right)^{*} \oplus \operatorname{Sha}^{1}\left(\mathbb{Q}_{p}\left(\bar{\chi}^{2-n}\right)\right)^{*} .
\end{aligned}
$$

However, using the inflation-restriction exact sequence, we get

$$
\operatorname{Sha}^{1}\left(\mathbb{Q}_{p}\left(\chi^{2-n}\right)\right) \simeq \underset{\Lambda}{\operatorname{Hom}}\left(A \otimes \mathbb{Q}, \mathbb{Q}_{p}\left(\chi^{2-n}\right)\right),
$$

where $A$ is the Galois group of the maximal unramified pro- $p$ extension of $K\left(E\left[\pi^{\infty}\right]\right)$ split above the primes dividing $T$. Now, by [6], we know that the $p$-adic $L$-function $\mathscr{L}$ annihilates $A \otimes \mathbb{Q}$. On the other hand, $\Lambda$ acts on $\mathbb{Q}_{p}\left(\chi^{2-n}\right)$ through the character $\chi^{2-n}$ and we know $\chi^{2-n}(\mathscr{L}) \neq 0$ for $n$ sufficiently large. Therefore,

$$
\underset{\Lambda}{\operatorname{Hom}}\left(A \otimes \mathbb{Q}, \mathbb{Q}_{p}\left(\chi^{2-n}\right)\right)=0
$$

for $n \gg 0$. There is a parallel argument for $\operatorname{Sha}^{1}\left(\mathbb{Q}_{p}\left(\bar{\chi}^{2-n}\right)\right)$ which then yields Claim 3.1. For Claim 3.2, the argument is exactly the same, except that the refined nonvanishing hypothesis implies

$$
\operatorname{Sha}^{1}\left(\mathbb{Q}_{p}\left(\chi^{2-n}\right)\right) \oplus \operatorname{Sha}^{1}\left(\mathbb{Q}_{p}\left(\bar{\chi}^{2-n}\right)\right)=0
$$

for $n \geq 3$.
Acknowledgements. It is a pleasure to express my gratitude to Kazuya Kato, Shinichi Mochizuki, Akio Tamagawa, Takeshi Tsuji and, especially, John Coates, conversations with whom were crucial to the formation of this paper.

## ISSN 0003-486X <br> Annals of Mathematics

This periodical is published bimonthly by the Department of Mathematics at Princeton University with the cooperation of the Institute for Advanced Study. Annals is typeset in $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ by Sarah R. Warren and produced by Mathematical Sciences Publishers. The six numbers each year are divided into two volumes of three numbers each.

## Editorial correspondence

Papers submitted for publication and editorial correspondence should be addressed to Maureen Schupsky, Annals of Mathematics, Fine Hall-Washington Road, Princeton University, Princeton, NJ, 08544-1000 U.S.A. The e-mail address is annals @ math.princeton.edu.

## Preparing and submitting papers

The Annals requests that all papers include an abstract of about 150 words which explains to the nonspecialist mathematician what the paper is about. It should not make any reference to the bibliography. Authors are encouraged to initially submit their papers electronically and in PDF format. Please send the file to: annals@math.princeton.edu or to the Mathematics e-print arXiv: front.math.ucdavis.edu/submissions. If a paper is submitted through the arXiv, then please e-mail us with the arXiv number of the paper.

## Proofs

A PDF file of the galley proof will be sent to the corresponding author for correction. If requested, a paper copy will also be sent to the author.

## Offprints

Authors of single-authored papers will receive 30 offprints. (Authors of papers with one co-author will receive 15 offprints, and authors of papers with two or more co-authors will receive 10 offprints.) Extra offprints may be purchased through the editorial office.

## Subscriptions

The price for a print and online subscription, or an online-only subscription, is $\$ 390$ per year for institutions. In addition, there is a postage surcharge of $\$ 40$ for print subscriptions that are mailed to countries outside of the United States. Individuals interested in subscriptions for their own personal use should contact the publisher at the address below. Subscriptions and changes of address should be sent to Mathematical Sciences Publishers, Department of Mathematics, University of California, Berkeley, CA 94720-3840 (e-mail: contact@mathscipub.org; phone: 1-510-643-8638; fax: 1-510-295-2608). (Checks should be made payable to "Mathematical Sciences Publishers".)

## Back issues and reprints

Orders for missing issues and back issues should be sent to Mathematical Sciences Publishers at the above address. Claims for missing issues must be made within 12 months of the publication date. Online versions of papers published five or more years ago are available through JSTOR (www.jstor.org).

## Microfilm

Beginning with Volume 1, microfilm may be purchased from NA Publishing, Inc., 4750 Venture Drive, Suite 400, PO Box 998, Ann Arbor, MI 48106-0998; phone: 1-800-420-6272 or 734-3026500; email: info@napubco.com, website: www.napubco.com/contact.html.

## TABLE OF CONTENTS

Denis Osin. Small cancellations over relatively hyperbolic groups and embedding theorems ..... 1-39
Haruzo Hida. The Iwasawa $\mu$-invariant of $p$-adic Hecke $L$-functions ..... 41-137
Irene I. Bouw and Martin Möller. Teichmüller curves, triangle groups, and Lyapunov exponents ..... 139-185
Igor Rodnianski and Jacob Sterbenz. On the formation of singularities in the critical $O(3) \sigma$-model ..... 187-242
Yuan-Pin Lee, Hui-Wen Lin and Chin-Lung Wang. Flops, motives, and invariance of quantum rings ..... 243-290
László Erdős, Benjamin Schlein and Horng-Tzer Yau. Derivation of the Gross-Pitaevskii equation for the dynamics of Bose-Einstein condensate ..... 291-370
L. Hakan Eliasson and Sergei B. Kuksin. KAM for the nonlinear Schrödinger equation ..... $371-435$
Miriam Briskin, Nina Roytvarf and Yosef Yomdin. Center conditions at infinity for Abel differential equations ..... 437-483
Igor Krichever. Characterizing Jacobians via trisecants of the Kummer variety ..... 485-516
Marc Burger, Alessandra Iozzi and Anna Wienhard. Surface group representations with maximal Toledo invariant ..... 517-566
Tim Dokchitser and Vladimir Dokchitser. On the Birch-Swinnerton-Dyer quotients modulo squares ..... 567-596
Dmitri Beliaev and Stanislav Smirnov. Random conformal snowflakes ..... 597-615
Sourav Chatterjee, Ron Peled, Yuval Peres and Dan Romik. Gravitational allocation to Poisson points ..... 617-671
Radu Laza. The moduli space of cubic fourfolds via the period map ..... 673-711
Narutaka Ozawa and Sorin Popa. On a class of $\mathrm{II}_{1}$ factors with at most one Cartan subalgebra ..... 713-749
Minhyong Kim. p-adic $L$-functions and Selmer varieties associated to elliptic curves with complex multiplication ..... 751-759
